BANACH SPACES FOR PIECEWISE CONE HYPERBOLIC MAPS

VIVIANE BALADI AND SÉBASTIEN GOUÉZEL

Abstract. We consider piecewise cone hyperbolic systems satisfying a bunching condition and we obtain a bound on the essential spectral radius of the associated weighted transfer operators acting on anisotropic Sobolev spaces. The bunching condition is always satisfied in dimension two, and our results give a unifying treatment of the work of Demers-Liverani [DL08] and our previous work [BG09]. When hyperbolicity dominates complexity, our bound implies a spectral gap for the transfer operator corresponding to the physical measures.

1. Introduction

The “spectral” or “functional” approach to study statistical properties of dynamical systems with enough hyperbolicity, originally limited to one-dimensional dynamics, has greatly expanded its range of applicability in recent years. The following spectral gap result of Blank–Keller–Liverani [BKL02] appeared in 2002:

Theorem 1.1. Let $T : X \to X$ be a $C^3$ Anosov diffeomorphism on a compact Riemannian manifold, with a dense orbit. Define a bounded linear operator by

$$L\omega = \frac{\omega \circ T^ {-1}}{|\det DT \circ T^{-1}|}, \quad \omega \in L^\infty(X).$$

Then there exist a Banach space $B$ of distributions on $X$, containing $C^\infty(X)$, and a bounded operator on $B$, coinciding with $L$ on $B \cap L^\infty(X)$ and denoted also by $L$, with the following properties: The spectral radius of $L$ on $B$ is equal to one, the essential spectral radius of $L$ on $B$ is strictly smaller than one, $L$ has a fixed point in $B$. Finally, 1 is the only eigenvalue on the unit circle, and it is simple.

It is a remarkable fact that “Perron-Frobenius-type” spectral information as in the above theorem (possibly with a nonsimple real maximal eigenvalue of finite multiplicity and other eigenvalues on the unit circle) gives simpler proofs of many known theorems, but also new information. Among these consequences, let us just mention: Existence of finitely many physical measures whose basins have full measure (working with slightly more general transfer operators, one can treat other equilibrium states), exponential decay of correlations for physical measures and Hölder observables, statistical and stochastic stability, linear response and the linear response formula, central and local limit theorems, location of the poles of
One of the advantages of this “functional approach” is that it bypasses the construction of Markov partitions and the need to introduce artificial “one-sided” expanding endomorphisms (such endomorphisms only retain a small part of the smoothness of the original hyperbolic diffeomorphism).

Billiards with convex scatterers, also called Sinai billiards, are among the most natural and interesting dynamical systems. They are uniformly hyperbolic, preserve Liouville measure, but they are only piecewise smooth. Analyzing the difficulties posed by the singularities has been an important challenge for mathematicians, and it is only in 1998 that L.-S. Young [You98] proved that the Liouville measure enjoys exponential decay of correlations for two-dimensional Sinai billiards (under a finite horizon condition, which was shortly thereafter removed by Chernov [Che99]). It should be noted that these results were in fact obtained for a discrete-time version of the billiard flow. Indeed the question of whether the original two-dimensional continuous-time Sinai billiard enjoys decay of correlations is to this day still open. (Chernov [Che07] recently obtained stretched exponential upper bounds.) It is well known that the continuous-time case is much more difficult, and it seems that the ideas of Dolgopyat [Dol98] which were exploited in several smooth hyperbolic situations are not compatible with the tools used in [You98] for example. We believe that a new, “functional,” proof (via a spectral gap result for the transfer operator (1.1) on a suitable anisotropic Banach space of distributions) of exponential decay of correlations for discrete-time surface Sinai billiards will be a key stepping stone towards the expected proof of exponential decay of correlations for the continuous-time Sinai billiards.

The recent paper of Demers-Liverani [DL08] was a first breakthrough in this direction, as we explain next. Since none of the spaces of [GL06, GL08, BT07, BT08] behave well with respect to multiplication by characteristic functions of sets, they cannot be used for systems with singularities. Demers–Liverani [DL08] therefore introduced some new Banach spaces, on which transfer operators associated to two-dimensional piecewise hyperbolic systems admit a spectral gap. However, the construction and the argument of [DL08] are quite intricate, in particular, pieces of stable or unstable manifolds are iterated by the dynamics, and the way they are cut by the discontinuities has to be studied in a very careful way, in the spirit of [You98] and [Che99]. As a consequence, adapting the approach in [DL08] to billiards (which are not piecewise hyperbolic, stricto sensu, because their derivatives blow up along the singularity lines) is daunting.

Another progress in the direction of a modern proof of exponential decay of correlations for discrete-time billiards is our previous paper [BG09]. There, we showed that ideas of Strichartz [Str67] imply that classical anisotropic Sobolev spaces $H^s_{p,a}$ in the Triebel-Lizorkin class [Tri77] (Definition 2.6, these spaces had been introduced in dynamics in [Ba05]) are suitable for piecewise hyperbolic systems, under the condition that the system admits a smooth (at least $C^1$) stable foliation. Unfortunately, although it holds for several nontrivial examples, this condition is pretty restrictive: In general, the foliations are only measurable!

In the present paper, we consider piecewise smooth and hyperbolic dynamics. We are able to remove the assumption of smoothness of the stable foliation, whenever the hyperbolicity exponents of the system satisfy a bunching condition (see (2.3) and (2.4) below). This condition is rather standard in smooth hyperbolic dynamics, where it ensures that the dynamical foliations are $C^2$ instead of the weaker Hölder condition which holds in full generality (see [HPS77], or, e.g., [HK95]). The bunching condition is always satisfied in codimension one (in particular, it holds
in dimension two, so that our results apply to all surface piecewise hyperbolic sys-

tems previously covered in [You98] or [DL08], in particular to hyperbolic Lozi maps

possessing a compact invariant domain). The present paper requires the dynamics
to be $C^{1+\alpha}$ on each (closed) domain of smoothness, and therefore does not apply
directly to discrete-time Sinai billiard. However, we expect that it will be possible to
adapt the methods here to obtain the desired functional proof of exponential decay
of correlations for two-dimensional Sinai billiards. We shall use the terminology
“cone-hyperbolic” to stress that hyperbolicity is defined in terms of cones and that
there is a priori no invariant stable distribution, contrary to our previous paper
[BG09].

We use the Triebel spaces $H^{t,s}_p$ as building blocks in the construction of our new
Banach spaces $H^{t,s}_p(R)$ (Definition 2.12) and $H$ (see (2.20)). As a consequence, we
may exploit, as we did in [BG09], the rich existing theory (in particular regarding
interpolation), and use again the results of Strichartz [Str67].

The new ingredient with respect to [BG09] is that we define our norm by consid-
ering the Triebel norm in $\mathbb{R}^d$ through suitable $C^1$ charts, taking now the suprema
over all cone-admissible charts $F$ (Definition 2.7). We use the bunching assump-
tion to show that the family is invariant under iteration (Lemma 3.3). Indeed, this is
how we avoid the necessity for a smooth stable foliation. As in [BG09], we do not
iterate single stable or unstable manifolds (contrary to [You98, Che99, DL08]), and
we do not need to match nearby stable or unstable manifolds: Everything follows
from an appropriate functional analytic framework.

Our main result, Theorem 2.5, is an upper bound on the essential spectral radius
of weighted transfer operators associated to cone hyperbolic systems satisfying the
bunching condition and acting on a Banach space $H$ of anisotropic distributions.
When the transfer operator is (1.1) (i.e., the weight is $|\det DT^{-1}|$, corresponding to
the physical measures), it suffices that hyperbolicity dominates complexity growth
(as measured by (2.2)) to get an essential spectral radius strictly smaller than 1,
and thus a spectral gap. This spectral gap property gives finiteness and exponential
mixing (up to a finite period) of the physical measures, modulo standard arguments
(see Theorem 33 from [BG09]).

Let us mention here that all existing results on piecewise hyperbolic systems,
including the present one, require some kind of transversality condition between
the discontinuity hypersurfaces and the stable or unstable dynamical directions or
cones (see Definition 2.3). (This condition is satisfied for billiards.)

The paper is organized as follows. In Section 2 we define formally the dynamical
systems for which our results hold and the anisotropic spaces $H$ on which the
transfer operator will act: Subsection 2.1 contains the assumptions on the dynamics
and the statement of our main result, Theorem 2.5. In Subsection 2.2, we recall the
definition of the Triebel spaces $H^{t,s}_p$ and we define the cone-admissible foliations
$F$. In Subsection 2.3, we combine these two ingredients, together with a “zoom”
by a large factor $R > 1$, to construct the Banach spaces of distributions $H^{t,s}_p(R)$.
Subsection 2.4 contains a technical step which reduces our main result to a more
convenient form, Theorem 2.14, constructing along the way the final Banach spaces
$H$ from the $H^{t,s}_p(R)$.

Section 3 is devoted to the proof of invariance of the class $F$ of admissible foliations.
This is the heart of our argument, and the main new technical ingredient
is Lemma 3.3. Its proof is based on the usual Hadamard-Perron graph transform
ideas (see (3.11)-(3.13)), but requires to be spelled out in full detail in order to
discover the appropriate conditions in Definition 2.7.

Section 4 contains various results on the local spaces $H^{t,s}_p$, in particular the corre-
sponding “Leibniz” (Lemma 4.1) and “chain-rule” (Lemmas 4.6 and 4.7) estimates,
and the fact that characteristic functions of appropriate sets are bounded multipliers (Lemma 4.2). These results are mostly adapted from [BG09]. Subsection 4.1 also contains a compactness embedding statement for spaces $H^{s}_{\alpha}(R)$ (Lemma 4.4) which is crucial for our Lasota-Yorke-type estimate in the proof of our main result.

Finally, Section 5 contains the proof of Theorem 2.14.

Note that the methods in this paper do not allow to exploit the additional smoothness available if $T$ is Anosov or Axiom A and $C^{r}$ for $r > 2$ (even if they satisfy the bunching condition), contrarily to [GL06, GL08, BT07, BT08]. The present work is thus complementary to the approach of [GL06, GL08, BT07, BT08] which gives more information in the smooth case (but fails when there are singularities).

2. Definitions and Statement of the Spectral Theorem

2.1. The main result. Let $X$ be a Riemannian manifold of dimension $d \geq 2$, and let $X_0$ be a compact subset of $X$. We view $1 \leq d_s \leq d - 1$ and $d_u = d - d_s \geq 1$ as being fixed integers, so constants may depend on these numbers.$^{2}$ We call $C^1$ hypersurface a codimension-one $C^1$ submanifold of $X$, possibly with boundary. We say that a function $g$ is $C^r$ for $r > 0$ if $g$ is $C^{[r]}$ and all partial derivatives of order $[r]$ are $r - [r]$-Hölder. The norm of a vector (in the tangent space of $X$, or in $\mathbb{R}^d$) will be denoted by $|v|$.

Hyperbolicity will be defined in terms of cones, and we shall need the cones to satisfy some form of convexity (in (3.8)). Even the simplest linear cone $|x|^2 \leq |y_1|^2 + |y_2|^2$ in $\mathbb{R}^3$ is not convex in the usual sense (it contains $(1, 1, 0)$ and $(1, 0, 1)$ but not $(1, 1/2, 1/2)$). Therefore, we introduce the following definition:

**Definition 2.1.** A subset $B$ of $\mathbb{R}^d$ is transverse to a vector subspace $E$ if $B \cap E = \{0\}$. It is convexly transverse to $E$ if, additionally, for all $z \in \mathbb{R}^d$, $B \cap (E + z)$ is convex.

A cone of dimension $d' \in [1, d-1]$ in $\mathbb{R}^d$ is a closed subset $C$ of $\mathbb{R}^d$ with nonempty interior, invariant under scalar multiplication, such that $d'$ is the maximal dimension of a vector subspace included in $C$.

Two cones $C_u$ and $C_s$, of respective dimensions $d_u$ and $d_s$, with $d_u + d_s = d$, are convexly transverse if, for any vector subspace $E_u \subset C_u$, the cone $C_u$ is convexly transverse to $E_u$ and for any vector subspace $E_s \subset C_s$, the cone $C_s$ is convexly transverse to $E_s$.

We claim that if $A : \mathbb{R}^{d_s} \to \mathbb{R}^k$ is an injective linear map then the set $C_A = \{(x, y) \in \mathbb{R}^{d_s} \times \mathbb{R}^d \mid |x| \leq |Ay| \}$ (which obviously contains the $d_s$-dimensional vector subspace $\{(0, y)\}$) is a $d_s$-dimensional cone which is convexly transverse to $\{(x, 0)\}$. See Appendix B for the easy proof of this claim and of the following corollary: If $C_A$ and $C_{A'}$ are cones in $\mathbb{R}^d$ associated (not necessarily for the same coordinates) to injective linear maps $A : \mathbb{R}^{d_s} \to \mathbb{R}^d$ and $A' : \mathbb{R}^{d_s} \to \mathbb{R}^d$, then $C_A$ and $C_{A'}$ are convexly transverse if and only if they are transverse in the usual sense (i.e., $C_A \cap C_{A'} = \{0\}$). Definition 2.1 is slightly more flexible than such linear cones. More importantly, it sheds light on the essence of the convexity assumption.

**Definition 2.2** (Piecewise $C^{1+\alpha}$ cone hyperbolic maps). Let $\alpha \in (0, 1]$. A piecewise $C^{1+\alpha}$ (cone) hyperbolic map is a map $T : X_0 \to X_0$ such that there exist finitely many pairwise disjoint open subsets $(O_i)_{i \in I}$, covering Lebesgue almost all $X_0$, so that each $\partial O_i$ is a finite union of $C^{\alpha}$ hypersurfaces, and so that for each $i \in I$:

1. There exists a $C^{1+\alpha}$ map $T_i$ defined on a neighborhood $\tilde{O}_i$ of $\partial O_i$, which is a diffeomorphism onto its image and such that $T|_{O_i} = T_i|_{\tilde{O}_i}$.

$^{2}$Our methods also work when $d_s = 0$ or $d_u = 0$, but they do not improve on the results of [BG09] since the stable and unstable manifolds are automatically smooth in this case.

$^{3}$In fact, injectivity of $A$ is not necessary: Take for example $d = 3, d_s = 2$, and $A(y_1, y_2) = y_1$. 

(2) There exist two families of convexly transverse cones $C_i^{(u)}(q)$ and $C_i^{(s)}(q)$ in the tangent space $T_qX$, depending continuously on $q \in \overline{O}_i$, so that $C_i^{(u)}(q)$ is $d_u$-dimensional and $C_i^{(s)}(q)$ is $d_s$-dimensional, and such that:

(2.a) For each $q \in \overline{O}_i \cap T_{i}^{-1}(\overline{O}_j)$, then $D_i(T_i(q))C_i^{(u)}(q) \subset C_j^{(u)}(T_i(q))$, and there exists $\lambda_{i,u}(q) > 1$ such that

$$|D_i(T_i(q))v| \geq \lambda_{i,u}(q)|v|, \forall v \in C_i^{(u)}(q).$$

(2.b) For each $q \in \overline{O}_i \cap T_{i}^{-1}(\overline{O}_j)$, then $D_i(T_i(q))C_j^{(s)}(T_i(q)) \subset C_i^{(s)}(q)$, and there exists $\lambda_{i,s}(q) < 1$ such that

$$|D_i(T_i(q))v| \geq \lambda_{i,s}^{-1}(q)|v|, \forall v \in C_j^{(s)}(T_i(q)).$$

Note that we do not assume that $T$ is continuous or injective on $X_0$.

We introduce some notation. For $n \geq 1$, and $i \in I^n$ we let $T^n_i = T_{i,n-1} \circ \cdots \circ T_{i,1}$, which is defined on a neighborhood of $O_i$, where $O_{(i_0)} = O_i$, and

$$O_{(i_0, \ldots, i_{n-1})} = \{ q \in O_{i_0} \mid T^n_i(q) \in O_{(i_1, \ldots, i_{n-1})} \}.$$ 

Denote by $\lambda^{(n)}(q) \in (0,1]$ and $\lambda^{(n)}(q) > 1$ the weakest contraction and expansion coefficients of $T^n_i$ at $q$, and by $\lambda^{(n)}_{k,s}(q) \leq \lambda^{(n)}_{i,s}(q)$ and $\Lambda^{(n)}_{k,u}(q) \geq \lambda^{(n)}_{i,u}(q)$ its strongest contraction and expansion coefficients. We put

$$\lambda_{i,s}(q) = \sup_{I \in O_i} \lambda^{(n)}_{i,s}(q) < 1, \quad \lambda_{u,n}(q) = \inf_{I, q \in O_i} \lambda^{(n)}_{i,u}(q) > 1.$$ 

As is usual in piecewise hyperbolic settings, we shall require a transversality assumption on the discontinuity hypersurfaces $\partial O_i$.

**Definition 2.3** (Transversality condition). Let $T$ be a piecewise $C^{1+\alpha}$ hyperbolic map. We say that $T$ satisfies the transversality condition if each $\partial O_i$ is a finite union of $C^1$ hypersurfaces $K_{i,k}$, such that $C_i^{(s)}(q) \cap T_qK_{i,k} = \{ 0 \}$ for all $q \in K_{i,k}$.

**Remark 2.4** (Transversality in the image). If all cones $C_i^{(s)}(q)$ coincide with a single continuous cone field $C^{(s)}(q)$, then we can weaken the requirements in the previous definition, replacing $\partial O_i$ by $T(\partial O_i)$. Indeed, if transversality with the image holds, then setting $C_i^{(s)}(q) := D_i(T_i(q))^{-1}(C^{(s)}(T_i(q)))$, the new cones $C_i^{(s)}$ are transverse to $\partial O_i$ and satisfy condition (2.b).

To estimate dynamical complexity, we define the $n$-complexities at the beginning and at the end:

$$D^b_n = \max_{q \in X_0} \text{Card}\{ i \in I^n \mid q \in \overline{O}_i \}, \quad D^e_n = \max_{q \in X_0} \text{Card}\{ i \in I^n \mid q \in \overline{O}_i \}.$$ 

Our main result can now be stated (all Jacobians in this paper are relative to Lebesgue measure, and $| \det DT|$ denotes the Jacobian of $T$):

**Theorem 2.5** (Spectral theorem). Let $\alpha \in (0,1]$, and let $T$ be a piecewise $C^{1+\alpha}$ cone hyperbolic map satisfying the transversality condition. Assume in addition the following bunching condition: For some $n > 0$,

$$\sup_{i \in I^n, q \in \overline{O}_i} \frac{\lambda^{(n)}_{i,s}(q)\lambda^{(n)}_{i,u}(q)}{\lambda^{(n)}_{i,u}(q)} < 1.$$ 

---

4 This condition is unrelated to the “convex transversality” assumption on the cones!

5 Condition (2.3) always holds if $d_u = 1$. 
Let $\beta \in (0, \alpha)$ be small enough so that
\begin{equation}
\sup_{i \in I_n, q \in O_i} \frac{\lambda^{(n)}_{L^{+}}(q)^{\alpha - \beta} \Lambda^{(n)}_{L^{+}}(q)^{1 + \beta}}{\lambda^{(n)}_{L^{-}}(q)} < 1.
\end{equation}
Let $1 < p < \infty$ and let $t, s \in \mathbb{R}$ be so that
\begin{equation}
1/p - 1 < s < t < 1/p, \quad -\beta < t - |s| < 0, \quad \alpha t + |s| < \alpha.
\end{equation}
Then there exists a space $\mathcal{H} = \mathcal{H}(p, t, s)$ of distributions on $X$, containing $C^1$ and in which $L^{\infty} \cap \mathcal{H}$ is dense, and such that for any function $g : X_{t} \rightarrow \mathbb{C}$ so that the restriction of $g$ to each $O_i$ admits a $C^\gamma$ extension to $\overline{O_i}$ for some $\gamma > t + |s|$, the operator $\mathcal{L}_g$ defined on $L^\infty$ by
\begin{equation}
(\mathcal{L}_g \omega)(q) = \sum_{T(q') = q} g(q') \omega(q'),
\end{equation}
extends continuously to $\mathcal{H}$. Moreover, its essential spectral radius on $\mathcal{H}$ is at most
\begin{equation}
\lim_{n \to \infty} (D^{\beta}_{n})^{1/(pn)} \cdot (D^{\alpha}_{n})^{(1/n)(1-1/p)} \cdot \left\| g^{(n)} \right\|_{L^n} \det DT^{n} \max(\lambda_{t,n}^{(1/t)}(\lambda_{x,n}^{(t-|s|)}))^{1/n},
\end{equation}
where we set $g^{(n)}(q) = \prod_{k=0}^{n-1} g(T^k(q))$, for $n \geq 1$.

Our proof does not give good bounds on the spectral radius of $\mathcal{L}_g$ on $\mathcal{H}$. However, if $g = \det DT^{-1}$ and the bound in (2.6) is $< 1$, then Theorem 33 in [BG09] implies that the spectral radius is equal to 1, and that $T$ has finitely many physical measures, attracting Lebesgue almost every point of the manifold.

The limit in (2.6) exists by submultiplicativity. We can bound $\lambda_{s,n}$ by $\lambda^{-n}$, where $\lambda > 1$ is the weakest rate of contraction/expansion of $T$. Therefore, if $g = \det DT^{-1}$ then the essential spectral radius is strictly smaller than 1 if there exist $s, t$ and $p$ as in Theorem 2.5 with
\begin{equation}
\lim_{n \to \infty} (D^{\beta}_{n})^{1/(pn)} \cdot (D^{\alpha}_{n})^{(1/n)(1-1/p)} \cdot \left\| \det DT^{n} \right\|_{L^n}^{1/p - 1} < \lambda_{\min(t, -(t-|s|))}.
\end{equation}
In particular, if $g = \det DT^{-1} \equiv 1$, then the essential spectral radius is strictly smaller than 1 if $\lim_{n \to \infty} (D^{\beta}_{n})^{1/(pn)} (D^{\alpha}_{n})^{(1/n)(1-1/p)} \leq \lambda_{\min(t, -(t-|s|))}$, that is, if hyperbolicity dominates complexity.

Subsections 2.2 and 2.3 are devoted to the definition of spaces $H_{t,s}^{L^p}(R)$ which will give the space $\mathcal{H}$ of Theorem 2.5 via Proposition 2.15 (see (2.20)). Let us now describe briefly this space $\mathcal{H}$, which generalizes the spaces of [Bal05, BG09]. Intuitively, an element of $\mathcal{H}$ is a distribution which has $t$ derivatives in $L^p$ in all directions together with $s$ derivatives in $L^p$ in the stable direction. This amounts to $s + t$ derivatives in $L^p$ in the stable direction, and $t$ derivatives in the transverse “unstable” direction. Since $t > 0$ and $t + s = t - |s| < 0$, the transfer operator increases regularity in this space. The restriction $1/p - 1 < s < t < 1/p$ is designed so that this space is stable under multiplication by characteristic functions of nice sets (see [BG09, Lemma 23]) — this makes it possible to deal with discontinuous maps. If one assumes that there exists a $C^3$ stable direction, the above rough description can be made precise, using anisotropic Sobolev spaces: This was done in [BG09].

In our setting, there is in general not even a continuous stable direction, so we shall instead use a class of local foliations (with uniformly bounded $C^{1 + \beta}$ norms) compatible with the stable cones, and define our norm as the supremum of the anisotropic Sobolev norms over all local foliations in this class (Definition 2.12).

To ensure that the space so defined is invariant under the action of the transfer operator, one should make sure that the preimage under iterates of $T$ of a foliation

---

6The local spaces in Definition 2.6 are the same as those in [BG09].
in our class remains in our class: This is the content of our key Lemma 3.3. Since
we want those foliations to have bounded $C^1$ norm (otherwise, the argument for
anisotropic Sobolev norms fails), we need the bunching condition (2.3) to prove this
invariance. (In the smooth, i.e., Axiom A case, (2.3) would ensure that the stable
foliation is $C^1$ — see e.g. [HK95, §19.1] in the case $\alpha = 1$ — and the strengthening
(2.4) would even ensure that the stable foliation is $C^{1+\beta}$. In the general piecewise
smooth case, the foliation is only measurable, even if (2.3) holds.)

2.2. Anisotropic spaces $H^{t, s}_p$ in $\mathbb{R}^d$ and the class $\mathcal{F}(z_0, C^s)$ of local foliations.
In this subsection, we recall the anisotropic spaces $H^{t, s}_p$ in $\mathbb{R}^d$ (which were used in
[BG09]), and we define a class $\mathcal{F}$ of cone-admissible local foliations in $\mathbb{R}^d$
with uniformly bounded $C^{1+\beta}$ norms (in Lemma 3.3 we shall show that this class is
invariant under iterations of the dynamics). These are the two building blocks that
we shall use in Section 2.3 to define our spaces of distributions.

We write $z \in \mathbb{R}^d$ as $z = (x, y)$ where $x = (z_1, \ldots, z_d)$ and $y = (z_{d+1}, \ldots, z_d).
The subspaces $\{x\} \times \mathbb{R}^d_u$ of $\mathbb{R}^d$ will be referred to as the stable leaves in $\mathbb{R}^d$. We
say that a diffeomorphism of $\mathbb{R}^d$ preserves stable leaves if its derivative has this
property. For $r > 0$ and $z = (x, y) \in \mathbb{R}^d$, let us write $B(z, r) = \{(x', y') \mid |x' - x| \leq
r, |y' - y| \leq r\}$ and $B(r) = B(0, r)$. We denote the Fourier transform in $\mathbb{R}^d$ by
$F$. An element of the dual space of $\mathbb{R}^d$ will be written as $(\xi, \eta)$ with $\xi \in \mathbb{R}^{d_u}$ and
$\eta \in \mathbb{R}^{d_s}$.

The local anisotropic Sobolev spaces $H^{t, s}_p$ belong to a class of spaces first studied
by Triebel [Tri77]:

**Definition 2.6** (Sobolev spaces $H^{t, s}_p$ and $H^s_p$ in $\mathbb{R}^d$). For $1 < p < \infty$, and $t, s \in \mathbb{R}$,
let $H^{t, s}_p$ be the set of (tempered) distributions $w$ in $\mathbb{R}^d$ such that
\[(2.7) \quad \|w\|_{H^{t, s}_p} := \|F^{-1}(a_{t, s}Fw)\|_{L^p} < \infty,\]
where
\[(2.8) \quad a_{t, s}(\xi, \eta) = (1 + |\xi|^2 + |\eta|^2)^{t/2}(1 + |\eta|^2)^{s/2}.\]
For $1 < p < \infty$, $t \in \mathbb{R}$, the set $H^s_p = H^{t, 0}_p$ is the standard (generalized)
Sobolev space.

Triebel proved that rapidly decaying $C^{\infty}$ functions are dense in each $H^{t, s}_p$ (see
e.g. [BG09, Lemma 18]). In particular, we could equivalently define $H^{t, s}_p$ to be the
closure of rapidly decaying $C^{\infty}$ functions for the norm (2.7).

We shall work with local foliations indexed by points $m$ in appropriate finite
subsets of $\mathbb{R}^d$ (defined in (2.16) below). The following definition of the class of
foliations is the key new ingredient of the present work. We view $\alpha \in (0, 1]$ and
$\beta \in (0, \alpha]$ as fixed (like in the statement of Theorem 2.5) while the constant $C_0 >
10$ will be fixed once and for all, large enough for our purposes, in the proof of
Lemma 3.3.

**Definition 2.7** (Sets $\mathcal{F}(m, C^s)$ of cone-admissible foliations at $m \in \mathbb{R}^d$). Let $C^s$ be
a $d_s$-dimensional cone in $\mathbb{R}^d$, transverse to $\mathbb{R}^{d_u} \times \{0\}$, and let $m = (x_m, y_m) \in \mathbb{R}^d$.
The set $\mathcal{F}(m, C^s)$ of $C^s$-admissible local foliations at $m$ is the set of maps
\[\phi = \phi_F : B(m, C_0) \to \mathbb{R}^d, \quad \phi_F(x, y) = (F(x, y), y),\]
where $F : B(m, C_0) \to \mathbb{R}^{d_u}$ is $C^1$ and satisfies
\[(2.9) \quad (\partial_y F(z)w, w) \in C^s, \forall w \in \mathbb{R}^{d_u}, \forall z \in B(m, C_0), \quad F(x, y_m) = x, \forall x \in B(x_m, C_0),\]
and, for all \((x,y)\) and \((x',y')\) in \(B(m,C_0)\),
\[
(2.10) \quad |DF(x,y) - DF(x',y')| \leq \left(\frac{|y - y'|}{C_0^2}\right)^\alpha,
\]
\[
(2.11) \quad |DF(x,y) - DF(x',y)| \leq |x - x'|^\beta,
\]
and
\[
(2.12) \quad |DF(x,y) - DF(x',y') - DF(x',y) + DF(x',y')| \leq C_0^{-1}|x - x'|^\beta |y - y'|^{\alpha - \beta}.
\]

The set \(F(m,C^\alpha)\) is large, as we explain next: If the cone \(C^\alpha\) is \(d_s\)-dimensional and transverse to \(\mathbb{R}^{d_u}\), then it contains a \(d_s\)-dimensional vector subspace \(E\) which is transverse to \(\mathbb{R}^{d_u}\). Therefore, there exists a (possibly zero) linear map \(E : \mathbb{R}^{d_s} \to \mathbb{R}^{d_u}\) so that \(E = \{(Ew, w) : w \in \mathbb{R}^{d_s}\}\). It follows that the affine map \(F_E(x,y) = x + E(y - y_m)\) is such that \(\phi_{F_E} \in F(m,C^\alpha)\). Then, it is easy to see that if \(F\) is \(C^{1+\beta}\), with \(F(x,y_m) = F_E(x,y_m) = x\), and \(F\) is close enough to \(F_E\), then \(\phi_F \in F(m,C^\alpha)\). (To check (2.12), consider separately the cases \(|x - x'| \leq |y - y'|\) and \(|x - x'| > |y - y'|\).

We now collect easy but important consequences of the above definition. (See also the remarks at the end of this subsection about the technical conditions (2.10)–(2.12).) We shall see in Lemma 2.8 that the graphs \(\{(F(x,y),y) : |y - y_m| < C_0\}\) for \(|x - x_m| < C_0\) form a partition of a neighborhood of \(m\) of size proportional to \(C_0\) (through the \(R\)-zoomed charts to be introduced in Section 2.3, this will correspond to a neighborhood of size of the order of \(C_0/R\) in the manifold), and their tangent space is everywhere contained in \(C^\alpha\). The map \(F\) thus defines a local foliation (justifying the terminology), and the map \(\phi_F\) is a diffeomorphism straightening this foliation, i.e., the leaves of the foliation are the images of the stable leaves of \(\mathbb{R}^d\) under the map \(\phi_F\). The maps \(y \mapsto (F(x,y),y)\) for fixed \(x\) are sometimes called plaques, while \(x \mapsto F(x,y)\) for fixed \(y\) is the holonomy between the transversals of respective heights \(y_m\) and \(y\).)

The conditions in the definition up to (2.10) imply that the foliation defined by \(F\) is \(C^{1+\beta}\) along the leaves. Moreover, the next lemma shows that these conditions imply uniform bounds on \(F\) (independent of \(C_0\)).

**Lemma 2.8** (Admissible foliations are \(C^{1+\beta}\) foliations). For any \(d_s\)-dimensional cone \(C^\alpha\) transverse to \(\mathbb{R}^{d_u} \times \{0\}\), there exists a constant \(C_\#\) depending only on \(C^\alpha\) such that, for any \(C_0 > 0\), and any \(\phi_F \in F(m,C^\alpha)\), \(\phi_F\) is a diffeomorphism onto its image with \(\|\phi_F\|_{C^{1+\beta}} \leq C_\#\) and \(\|\phi_F^{-1}\|_{C^{1+\beta}} \leq C_\#\). Moreover, \(\phi_F(B(m,C_0))\) contains \(B(m,C_0^{-1}C_\#)\).

The proof of these claims does not require (2.12).

**Proof.** Let \(\phi = \phi_F \in F(m,C^\alpha)\). We first check \(\|F\|_{C^1} \leq C_\#\). Observe first that, \(\partial_x F\) is bounded since the cone \(C^\alpha\) is transverse to \(\mathbb{R}^{d_u} \times \{0\}\). Since \(F(x,y_m) = x\), we have \(\partial_x F(x,y_m) = \text{id}\), hence (2.10) gives
\[
(2.13) \quad |\partial_x F(x,y) - \text{id}| = |\partial_x F(x,y) - \partial_x F(x,y_m)| \leq (|y - y_m|/C_0^2)^\alpha \leq C_0^{-\alpha} \leq 10^{-\alpha} < 1.
\]
In particular, \(\partial_x F\) is uniformly bounded. This shows that \(\|F\|_{C^1} \leq C_\#\). We next observe that condition (2.11) together with (2.10) imply that \(DF\) is \(\beta\)-Hölder: There exists a constant \(C_\#\) (independent of \(C_0\)) such that
\[
(2.14) \quad |DF(x,y) - DF(x',y')| \leq C_\# d((x,y),(x',y'))^\beta,
\]
for all pairs \((x,y)\) and \((x',y')\) in \(B(m,C_0)\). Indeed, (2.10) gives \(|DF(x,y) - DF(x,y)| \leq |y - y'|^{\alpha}\), and (2.11) gives \(|DF(x,y) - DF(x',y)| \leq |x - x'|^\beta\). Since \(\beta \leq \alpha\), (2.14) follows. We have shown that \(\|\phi\|_{C^{1+\beta}} \leq C_\#\).
For any vector $v$, (2.13) shows that $\langle \partial_x Fv, v \rangle \geq \epsilon # |v|^2$, for $\epsilon # = 1 - 10^{-\alpha}$. Integrating this inequality on the segment between $x$ and $x'$, for $v = x' - x$, we get $\langle F(x, y) - F(x', y), x - x' \rangle \geq \epsilon # |x - x'|^2$. In particular,

$$
|F(x, y) - F(x', y)| \geq \epsilon # |x - x'|.
$$

(2.15)

By Lemma A.1, this implies that the map $\phi$ belongs to the class $\mathcal{D}(C_{\#})$ defined in Subsection A.1, for some $C_{\#} > 0$ independent of $C_0$. In particular, $\phi$ is a diffeomorphism onto its image, and $\|D\phi^{-1}\| \leq C_{\#}$. Since $D\phi$ is $\beta$-Hölder, it follows that $D\phi^{-1}$ is also $\beta$-Hölder, and $\|\phi^{-1}\|_{C^{1+\beta}} \leq C_{\#}$.

Finally, Lemma A.2 shows that $\phi(B(m, C_0))$ contains $B(\phi(m), C_{\#}^{-1} C_0)$. \qed

We end this subsection with the promised remarks on the conditions in Definition 2.7 involving $\alpha$ and $\beta$.

**Remark 2.9 (Condition (2.10)).** Condition (2.10) is used in the proof of Lemma 2.8 to ensure that $|DF|$ is uniformly bounded. It would seem more natural to replace (2.10) by the weaker condition $|DF| \leq C$. However, it turns out that this weaker condition is never invariant under the graph transform, while (2.10) is invariant if (2.3) is satisfied (see (3.11)). If $T$ is piecewise $C^2$ one can take $\alpha = 1$, and this is what is usually done in the literature ([HK95], [Liv04, App. A]). In addition, because of the extra $C^{1+\alpha}$ smoothness in the $y$-direction given by (2.10), Lemma 3.3 produces diffeomorphisms $\Psi$ and $\Psi_m$ which belong to the space $D^1_{1+\alpha}$ from Definition 3.1. This is useful in view of the composition Lemma 4.7.

**Remark 2.10 (Conditions (2.11) and (2.12); Hölder Jacobian).** Lemma 4.4 about compact embeddings requires the foliations $\phi_F$ and their inverses $\phi_F^{-1}$ to have $C^\beta$ Jacobians for some $\beta > 0$. (Beware that, even if $T$ is volume-preserving, the class of foliations satisfying $|\det D\phi| \equiv 1$ is not invariant under the dynamics, because of the necessary reparametrizations in the proof of Lemma 3.3.) Lemma 2.8 shows that the conditions (2.10) and (2.11) imply that the Jacobians $J(x, y) = |\det D\phi_F|(x, y) = |\det \partial_x F|(x, y)$ and $J'(x, y) = |\det D\phi_F^{-1}|(x, y)$ are $\beta$-Hölder (with a $C^\beta$ norm bounded independently of $C_0$).

Condition (2.11) will only be used to ensure that $J$ and $J'$ are $C^\beta$. It turns out that the Hölder condition on the Jacobians, by itself, is not preserved when the foliation is iterated under hyperbolic maps, and neither is the condition (2.11) alone. However, the pair (2.11)-(2.12) is invariant if (2.4) is satisfied (see in particular Step 3 in the proof of Lemma 3.3).

### 2.3. Extended cones, suitable charts and spaces of distributions

In this subsection, we introduce appropriate cones $C_{i,j}^I$ and coordinate patches $\kappa_{i,j}$ on the manifold in order to glue together (via a partition of unity) the local spaces $H^s_{p}^{\ast}$ and define a space $H^s_{p}^{\ast}(R)$ of distributions\(^7\) by using the charts in $F(m, C_{i,j}^I)$.

**Definition 2.11.** An extended cone $\mathcal{C}$ is a set of four cones $(C^s, C^u_0, C^u, C^s_0)$ such that $C^s$ and $C^u$ are convexly transverse, $C^s_0$ contains $\{0\} \times \mathbb{R}^d$, $C^u_0$ contains $\mathbb{R}^d \times \{0\}$ and $C^s_0 - \{0\}$ is contained in the interior of $C^s$, $C^u_0 - \{0\}$ is contained in the interior of $C^u$. Given two extended cones $\mathcal{C}$ and $\tilde{\mathcal{C}}$, we say that an invertible matrix $M : \mathbb{R}^d \rightarrow \mathbb{R}^d$ sends $\mathcal{C}$ to $\tilde{\mathcal{C}}$ compactly if $MC^s$ is contained in $\tilde{C^s}$, and $M^{-1}C^u$ is contained in $\tilde{C^u}$.

For all $i \in I$, we fix once and for all a finite number of open sets $U_{i,j,0}$ of $X_0$, for $1 \leq j \leq N_i$, covering $\mathcal{C}_i$, and included in the fixed neighborhood $\mathcal{O}_i$ of $\mathcal{O}_i$, where $T_i$ is defined. Let also $\kappa_{i,j} : U_{i,j,0} \rightarrow \mathbb{R}^d$, for $i \in I$ and $1 \leq j \leq N_i$, be a finite family of $C^\infty$ charts, and let $\mathcal{C}_{i,j}$ be extended cones in $\mathbb{R}^d$ such that, wherever

\(^7\)This is a modification of the space denoted $\tilde{H}^s_{p}^{\ast}$ in [BG09].
\(\kappa_{i,j}^{-1}\) is defined, its differential sends \(C_{i,j}\) to \(C_{i,j}^{-1}\) compactly. Such charts and cones exist: Take charts with small enough supports, and locally constant cones \(C_{i,j}^u\), \(C_{i,j}^d\) slightly larger than the cones \(C_i^u(q), C_i^d(q)\), and slightly smaller cones \(C_{i,j,0}, \tilde{C}_{i,j,0}\). (Convex transversality in the extended cone follows from our convex transversality assumption on \(C_i^u\) and \(C_i^d\).) We also fix open sets \(U_{i,j,1}\) covering \(X_0\) such that \(U_{i,j,1} \subseteq U_{i,j,0}\), and we let \(V_{i,j,k} = \kappa_{i,j}(U_{i,j,k})\), \(k = 0, 1\).

The spaces of distributions will depend on a large parameter \(R \geq 1\) which will play the part of a "zoom." If \(R \geq 1\) and \(W\) is a subset of \(\mathbb{R}^d\), denote by \(WR\) the set \(\{R \cdot z \mid z \in W\}\). Let also \(\kappa_{i,j}^R(q) = R\kappa_{i,j}(q)\), so that \(\kappa_{i,j}^R(U_{i,j,k}) = V_{i,j,k}^R\). Let

\[
Z_{i,j}(R) = \{m \in V_{i,j,0}^R \cap \mathbb{Z}^d \mid B(m, C_0) \cap V_{i,j,1}^R \neq \emptyset\},
\]

and

\[
Z(R) = \{(i, j, m) \mid i \in I, 1 \leq j \leq N, m \in Z_{i,j}(R)\}.
\]

To \(\zeta = (i, j, m) \in Z(R)\) is associated the point \(q_\zeta := (\kappa_{i,j}^R)^{-1}(m)\) of \(X\). These are the points around which we shall construct local foliations, as follows. Let us first introduce useful notations: We write

\[
O_\zeta = O_i, \quad \kappa_{i,j}^R = \kappa_{i,j}^R, \quad \mathcal{C}_\zeta = \mathcal{C}_{i,j} \quad \text{for } \zeta = (i, j, m) \in Z(R).
\]

These are respectively the partition set, the chart and the extended cone that we use around \(q_\zeta\). If \(R\) is large enough, say \(R \geq R_0\), then, for any \(\zeta = (i, j, m) \in Z(R)\) and any chart \(\phi_\zeta \in \mathcal{F}(m, \mathcal{C}_\zeta^d)\), we have \(\phi_\zeta(B(m, C_0) \cap V_{i,j,0}^R) \subseteq V_{i,j,0}^R\). For \(\zeta = (i, j, m) \in Z(R)\), we can therefore consider the set of charts (\(R\) does not appear in the notation for the sake of brevity)

\[
\mathcal{F}(\zeta) := \{\phi_\zeta = (\kappa_{i,j}^R)^{-1} \circ \phi_\zeta : B(m, C_0) \to X, \phi_\zeta \in \mathcal{F}(m, \mathcal{C}_\zeta^d)\}.
\]

The image under a chart \(\Phi_\zeta \in \mathcal{F}(\zeta)\) of the stable foliation in \(\mathbb{R}^d\) is a local foliation around the point \(q_\zeta\), whose tangent space is everywhere contained in \((D\kappa_{i,j}^R)^{-1}(\mathcal{C}_\zeta^r)\).

This set is almost contained in the stable cone \(C_{i,j}^s\), by our choice of charts \(\kappa_{i,j}\) and extended cones \(\mathcal{C}_{i,j}\).

Let us fix once and for all a \(C^\infty\) function\(^8\) \(\rho : \mathbb{R}^d \to [0, 1]\) such that

\[
\rho(z) = 0 \text{ if } |z| \geq d \quad \text{and} \quad \sum_{m \in \mathbb{Z}^d} \rho(z - m) = 1.
\]

For \(\zeta = (i, j, m) \in Z(R)\), let \(\rho_m(z) = \rho(z - m)\), and

\[
\rho_\zeta := \rho_\zeta(R) = \rho_m \circ \kappa_{i,j}^R : X \to [0, 1].
\]

Since \(\rho_m\) is compactly supported in \(\kappa_{i,j}^R(U_{i,j,0})\) if \(m \in Z_{i,j}(R)\) (and \(R\) is large enough, depending on \(d\)), the above expression is well-defined. This gives a partition of unity in the following sense:

\[
\sum_{m \in Z_{i,j}(R)} \rho_{i,j,m}(q) = 1, \forall q \in U_{i,j,1}, \quad \rho_{i,j,m}(q) = 0, \forall q \notin U_{i,j,0}.
\]

Our choices ensure that the intersection multiplicity of this partition of unity is bounded, uniformly in \(R\), i.e., for any point \(q\), the number of functions such that \(\rho_\zeta(q) \neq 0\) is bounded independently of \(R\).

The space we shall consider depends in an essential way on the parameters \(p, t, \) and \(s\). It will also depend, in an inessential way, on the choices we have made (i.e., the reference charts \(\kappa_{i,j}\), the extended cones \(\mathcal{C}_{i,j}\), the constant \(C_0\), the function \(\rho\), and \(R \geq R_0\)): Different choices would lead to different spaces, but all such spaces share the same features. We only emphasize the dependence on \(R\) in the notations, since all the other choices will be fixed once and for all.

---

\(^8\)Such a function exists since the balls of radius \(d\) centered at points in \(\mathbb{Z}^d\) cover \(\mathbb{R}^d\).
Definition 2.12 (Spaces $H_{p}^{t,s}(R)$ of distributions on $X$). Let $1 < p < \infty$, $s,t \in \mathbb{R}$, and $R \geq R_0$. For any system of charts $\Phi = \{\Phi_{\zeta} \in \mathcal{F}(\zeta) \mid \zeta \in \mathcal{Z}(R)\}$, let

\begin{equation}
(2.18) \quad \|\omega\|_{\Phi, R} = \left( \sum_{\zeta \in \mathcal{Z}(R)} \|\rho_{\zeta}(R) \cdot 1_{O_{\zeta}} \cdot \Phi_{\zeta}\|_{H_{p}^{t,s}(R)}^{p} \right)^{1/p},
\end{equation}

and put $\|\omega\|_{H_{p}^{t,s}(R)} = \sup_{\Phi} \|\omega\|_{\Phi, R}$, the supremum ranging over all such systems of charts $\Phi$.

The space $H_{p}^{t,s}(R)$ is the closure of $\{\omega \in L^{\infty}(X_0) \mid \|\omega\|_{H_{p}^{t,s}(R)} < \infty\}$ for the norm $\|\omega\|_{H_{p}^{t,s}(R)}$.

For fixed $R$, the sum in (2.18) involves a uniformly bounded number of terms. Since the charts $\Phi_{\zeta}$ have a uniformly bounded $C^1$ norm, the functions $(\rho_{\zeta}(R) \cdot \omega) \cdot \Phi_{\zeta}$ are uniformly bounded in $C^1$ if $\omega$ is $C^1$. Moreover, $H_{p}^{t,s}(R)$ contains the space of compactly supported $C^1$ functions on $\mathbb{R}^d$ when $|t| + |s| \leq 1$. Therefore, if there were no multiplication by $1_{O_{\zeta}}$ in (2.18), then $\|\omega\|_{H_{p}^{t,s}(R)}$ would be finite for any $C^1$ function $\omega$. When $s,t \in (1/p - 1, 1/p)$, multiplication by $1_{O_{\zeta}} \cdot \Phi_{\zeta}$ leaves the space $H_{p}^{t,s}$ invariant (see Lemma 4.2 below). Therefore, all $C^1$ functions belong to $H_{p}^{t,s}(R)$ in this case.

Remark 2.13. Note that $H_{p}^{t,s}(R)$ is not isomorphic to a Triebel space $H_{p}^{t,s}(X_0)$. However, our assumptions ensure that $H_{p}^{t,s}(R)$ is isomorphic to the Sobolev-Triebel space $H_{p}^{t,s}(X_0)$ (whatever the value of $R$) when $-\beta < t < 1 + \beta$. See Lemma 4.4 for various embedding claims on the $H_{p}^{t,s}(R)$.

2.4. Reduction of the main result. In this subsection, we shall deduce Theorem 2.5 from the following result about the spaces introduced in Subsection 2.3:

Theorem 2.14. Let $T$, $g$, and $p$, $t$, $s$ satisfy the assumptions of Theorem 2.5. There exist a constant $C_g > 0$ and an integer $n_0$ such that for any $n \geq n_0$ there exists $R(n)$ so that if $R \geq R(n)$ then the operator $L^{n}_{g}$ is bounded on $H_{p}^{t,s}(R)$, and its essential spectral radius is at most

\begin{equation}
C_g n(D^{n}_{g})^{1/p} \cdot (D^{n}_{g})^{1-1/p} \cdot \|g^{n}\| \cdot \det DT^{n} \cdot \max(\lambda^{-1}_{a,n}, \lambda^{-1}_{s,n}(t-|s|)) \|L^{n}_{g}\|_{L^{\infty}}.
\end{equation}

The above theorem will be proved in Section 5. Below, we deduce Theorem 2.5 from Theorem 2.14, using the following proposition (which will be proved at the end of Section 5).

Proposition 2.15. Let $T$, $g$, and $p$, $t$, $s$ satisfy the assumptions of Theorem 2.5. There exists $R_1 > 0$ such that, for any $R, R' \geq R_1$, there exists an integer $N_0$ such that for any $N \geq N_0$ the operator $L^{n}_{g}$ is continuous from $H_{p}^{t,s}(R)$ to $H_{p}^{t,s}(R')$.

Proof that Theorem 2.14 implies Theorem 2.5. Theorem 2.14 does not claim that the space $H_{p}^{t,s}(R)$ is invariant under $L_{g}$. This issue is easy to deal with: Let $H(n, R) = H(p, t, s, n, R)$ be the closure of $L^{\infty}(X_0)$ for the norm

\begin{equation}
(2.20) \quad \|\omega\|_{H(p, t, s, n, R)} = \sum_{k=0}^{n-1} \|L^{k}_{g} \omega\|_{H_{p}^{t,s}(R)}. \quad \text{Since} \quad \|L^{k}_{g} \omega\|_{H_{p}^{t,s}(R)} \leq C \|\omega\|_{H_{p}^{t,s}(R)}, \text{it follows from Theorem 2.14 that the operator} \quad L_{g} \text{is continuous on} \quad H(n, R). \quad \text{Moreover, for any} \quad C^1 \text{function} \quad \omega, \quad \text{the function} \quad L^{k}_{g} \omega \text{belongs to} \quad H_{p}^{t,s}(R) \text{for any} \quad k \geq 0. \quad \text{This follows from the discussion following Definition 2.12. Hence,} \quad H(n, R) \text{contains} \quad C^1.
To finish, we shall prove that the claim on the essential spectral radius of $L_g$ holds on $H = H(n, R)$, if $n$ and $R$ are large enough. If $\mathcal{M}$ is an operator acting on a Banach space $E$, we denote by $r_{\text{ess}}(\mathcal{M}, E)$ its essential spectral radius.

**First claim:** $r_{\text{ess}}(L_g, H(n, R)) \leq \frac{1}{n} \frac{C^*}{|\mu|} |g|^{1/n} \|\det DT^n\|^{1/p} \max(\lambda_{-t}^{-1}, \lambda_{-t}^{-1/|s|})\|L_g\|_{L^\infty}^{1/n}$.

Since $(C^*|\mu|n)^{1/n}$ tends to 1 when $n \to \infty$, this factor is not troublesome. However, we do not have Theorem 2.5 yet: In (2.6), there is a limit in $n$, while our last bound is for a fixed $n$. This is why we need to show the following statement:

**Second claim:** Let $r$ be the limit in (2.6). For $n \geq n_0$ and $R \geq \max(R_1, R(n))$, we have $r_{\text{ess}}(L_g^n, H^{t,s}_{p,s}(R)) \leq r^n$.

Putting together the first and second claims we have that for any $n \geq n_0$ and $R \geq \max(R_1, R(n))$ the space $H = H(n, R)$ satisfies the conclusion of Theorem 2.5.

It remains to prove the two above claims. For this, we recall a characterization of the essential spectral radius of an operator $\mathcal{M}$ acting on a Banach space $E$.

1. Let $\tau > 0$, assume that there exist a sequence $j(n) \to \infty$ and a sequence of compact operators $K_n : E \to E_n$ (for some Banach spaces $E_n$) such that $\|\mathcal{M}^{j(n)}w\|_E \leq \tau^{j(n)} \|w\|_E + \|K_nw\|_{E_n}$ for any $w \in E$ (or, equivalently, in a dense subset of $E$) and any large enough $n$. Then $r_{\text{ess}}(\mathcal{M}, E) \leq \tau$.

2. Conversely, if $\tau > r_{\text{ess}}(\mathcal{M}, E)$, there exists a sequence of compact operators $K_n : E \to E$ such that, if $n$ is large enough, $\|\mathcal{M}^nw\|_E \leq \tau^n \|w\|_E + \|K_nw\|_E$ for any $w \in E$.

The first assertion was proved by Hennion [Hen93] using a formula of Nussbaum. The second assertion follows from the spectral decomposition $\mathcal{M} = K + A$ where $KA = AK = 0$, $K$ has finite rank (and corresponds to the eigenvalues of $\mathcal{M}$ of modulus greater than $\tau$), and the spectral radius of $A$ is smaller than $\tau$ (just take $K_n = K^n$).

We now prove the first claim. Let $\tau > r_{\text{ess}}(L_g^n, H^{t,s}_{p,s}(R))$. By Item 2, there exists a sequence of compact operators $K_{kn} : H^{t,s}_{p,s}(R) \to H^{t,s}_{p,s}(R)$ such that, for large enough $k$, $\|L_g^{kn}w\|_{H^{t,s}_{p,s}(R)} \leq \tau^{kn} \|w\|_{H^{t,s}_{p,s}(R)} + \|K_{kn}w\|_{H^{t,s}_{p,s}(R)}$. Therefore, for $\omega \in H(n, R)$,

$$\|L_g^{kn}\omega\|_{H(n, R)} \leq \sum_{j=0}^{n-1} \|L_g^{kn}L_g^j\omega\|_{H^{t,s}_{p,s}(R)} \leq \sum_{j=0}^{n-1} \tau^{kn} \|L_g^j\omega\|_{H^{t,s}_{p,s}(R)} + \|K_{kn}L_g^j\omega\|_{H^{t,s}_{p,s}(R)} = \tau^{kn} \|\omega\|_{H(n, R)} + \|\widetilde{K}_{kn}\omega\|_{H^{t,s}_{p,s}(R)^n},$$

where the operator $\widetilde{K}_{kn}$ from $H(n, R)$ to $H^{t,s}_{p,s}(R)^n$ is given by

$$\widetilde{K}_{kn}\omega = (K_{kn}\omega, K_{kn}L_g\omega, \ldots, K_{kn}L_g^{n-1}\omega).$$

Since this operator is compact, Item 1 above gives that $r_{\text{ess}}(L_g, H(n, R)) \leq \tau$, and thus the first claim.

Finally, we prove the second claim. The idea is to use Proposition 2.15 to go from $H^{t,s}_{p,s}(R)$ to $H^{t,s}_{p,s}(R')$ for a large $R'$, use the good control on the essential spectral radius on $H^{t,s}_{p,s}(R')$, and then return to $H^{t,s}_{p,s}(R)$. Let $n$ and $R$ be as in the statement of the second claim. Consider $\tau > r$, and let us fix $k > 0$ and $R' > R_1$ such that $r_{\text{ess}}(L_g^{kn}, H^{t,s}_{p,s}(R')) < \tau^{kn}$. This is possible by Theorem 2.14. Therefore, by Item 2, for large $j$, there exists a compact operator $K_{jkn} : H^{t,s}_{p,s}(R') \to H^{t,s}_{p,s}(R')$ such that $\|L_g^{kn}\omega\|_{H^{t,s}_{p,s}(R')} \leq \tau^{kn} \|\omega\|_{H^{t,s}_{p,s}(R')} + \|K_{jkn}\omega\|_{H^{t,s}_{p,s}(R')}$. By Proposition 2.15, we can
choose \( m \) such that the operator \( L^{m+n}_{g} \) sends \( H^{t,s}_{p}(R) \) to \( H^{t,s}_{p}(R') \) continuously, with a norm bounded by a constant that we denote by \( C \). Then, for any \( \omega \in H^{t,s}_{p}(R) \),

\[
\| \mathcal{L}^{(k+2)m+n}_{g}(\omega) \|_{H^{t,s}_{p}(R')} \leq C \| \mathcal{L}^{(k+m)n}_{g}(\omega) \|_{H^{t,s}_{p}(R')} + \| K_{jkn} L^{mn}_{g}(\omega) \|_{H^{t,s}_{p}(R')} \leq C^{2} \tau^{jkn} \| \omega \|_{H^{t,s}_{p}(R')} + \| K_{jkn} L^{mn}_{g}(\omega) \|_{H^{t,s}_{p}(R')} \frac{1}{\tau}. \]

Since the operator \( \mathcal{K}_{jkn} := K_{jkn} C^{mn}_{g} \) is compact from \( H^{t,s}_{p}(R) \) to \( H^{t,s}_{p}(R') \), Item 1 ensures that

\[
\tau_{\text{ess}}(\mathcal{L}^{m}_{g}, H^{t,s}_{p}(R)) \leq \lim_{n \to \infty} \inf (C^{2} \tau^{jkn})^{1/(j+2m)} = \tau. \]

This ends the proof of the second claim and of the theorem.

\[ \square \]

3. Invariance of the class of cone admissible local foliations

In order to prove the bounds necessary for Theorem 2.14, we need to check that the class of admissible foliations defined in Subsection 2.2 is invariant under the iteration of the map \( T^{-1} \) (viewed in charts). This is the purpose of the key Lemma 3.3 below, which says that if \( \phi_{m} \in \mathcal{F}(m, C^{\tau}) \) is an admissible foliation, then the chart \( \phi' \) obtained by pulling it back by a diffeomorphism \( T^{-1} \) of \( \mathbb{R}^{d} \), and reparameterizing to put it in standard form is still admissible if the map \( T \) is sufficiently hyperbolic, \( C^{1+\alpha} \), and satisfies a bunching condition (see (3.1)). This fact is not surprising: It is well known (see e.g. the Hadamard-Perron arguments in [HK95, §6.2, §19]) that \( C^{4} \) foliations remain \( C^{4} \) after a graph transform if the transformation satisfies a bunching condition. However, the statement of Lemma 3.3 is a little involved because (in order to avoid exponential proliferation of the number of charts) we need to “glue together” all pulled back charts \( \phi_{m} \) associated to a set \( M \) of “well-separated” points \( m \). This must be done carefully, controlling the size of the domains of definition of the new chart \( \phi' \) thus produced.

If the pullback of a foliation \( \phi(x,y) = (F(x,y),y) \) under a map \( T \) is given in standard form by a map \( \phi'(x,y) = (F'(x,y),y) \), this means that \( T^{-1} \circ \phi = \phi' \circ T \) for some map \( T \) defined on a subset of \( \mathbb{R}^{d} \), and sending stable leaves to stable leaves. This map \( T \) is needed to straighten \( T^{-1} \circ \phi \) which typically does not have the form \( (x,y) \mapsto (F'(x,y),y) \). The map \( T \) corresponds to \( T^{-1} \) in the charts \( \phi, \phi' \), and it will be important to control well its smoothness and hyperbolicity. In particular, the following definition will be useful.

**Definition 3.1.** For \( C > 0 \) let \( D^{1+\alpha}_{1}(C) \) denote the set of \( C^{1} \) diffeomorphisms \( \Psi \) defined on a subset of \( \mathbb{R}^{d} \), sending stable leaves to stable leaves, and such that

\[
\max(\sup_{x} |D\Psi(x,y)|, \sup_{x} |D\Psi^{-1}(x,y)|, \sup_{x} \frac{|D\Psi(x,y) - D\Psi(x,y')|}{|y-y'|^{\alpha}}) \leq C. \]

Before we state Lemma 3.3, we need one more notation:

**Definition 3.2.** Let \( C \) and \( \tilde{C} \) be extended cones (Definition 2.11). If an invertible matrix \( M : \mathbb{R}^{d} \to \mathbb{R}^{d} \) sends \( C \) to \( \tilde{C} \) compactly, let \( \lambda_{u}(M) = \lambda_{u}(M, C, \tilde{C}) \) be the least expansion under \( M \) of vectors in \( C^{\tau} \), and \( \lambda_{s}(M) = \lambda_{s}(M, C, \tilde{C}) \) be the inverse of the least expansion under \( M^{-1} \) of vectors in \( \tilde{C}^{\tau} \). Denote by \( \lambda_{u}(M) = \lambda_{u}(M, C, \tilde{C}) \) and \( \lambda_{s}(M) = \lambda_{s}(M, C, \tilde{C}) \) the strongest expansion and contraction coefficients of \( M \) on the same cones.

The key lemma can now be stated:
Lemma 3.3. Let $C$ and $\tilde{C}$ be extended cones, let $\alpha \in (0, 1]$ and let $\beta \in (0, \alpha)$. For any large enough $C_0$ (depending on $C$ and $\tilde{C}$), there exist constants (depending on $C$, $\tilde{C}$ and $C_0$) $\lambda$ and $\epsilon$ satisfying the following properties:

Let $T$ be a $C^{1+\alpha}$ diffeomorphism of $\mathbb{R}^d$ with $T(0) = 0$ and, setting $\mathcal{M} := DT(0)$, so that

$$
\|T^{-1} \circ M - \text{id}\|_{C^{1+\alpha}} \leq \epsilon, \quad M \text{ sends } C \text{ to } \tilde{C} \text{ compactly,}
$$

(3.1)

$$
\lambda_u(M)^{\alpha-\beta} \lambda_u(M)^{1+\beta} \lambda_u(M)^{-1} < \epsilon, \quad \lambda_u(M) > C, \quad \lambda_u(M)^{-1} > C.
$$

Let $\mathcal{M} \subset \mathbb{R}^d$ be a finite set such that $|m - m'| \geq C$ for all $m \neq m' \in \mathcal{M}$, and consider any family of charts $\{\phi_m \in \mathcal{F}(m, C^s) \mid m \in \mathcal{M}\}$.

Then, defining

$$
\mathcal{M}' := \{m \in \mathcal{M} \mid B(m, d) \cap T(B(0, d)) \neq \emptyset\},
$$

and setting $\Pi(x, y) = (x, 0)$, we have:

(a) $\Pi m - \Pi m' \geq C_0$ for all $m \neq m'$ in $\mathcal{M}'$.

(b) There exist $\psi' \in \mathcal{F}(0, C^s)$, and diffeomorphisms $T_m$, for $m \in \mathcal{M}'$, such that

(3.2)

$$
T^{-1} \circ \phi_m = \psi' \circ T_m \quad \text{on } \phi_m^{-1}(B(m, d) \cap T(B(0, d))), \quad \forall m \in \mathcal{M}'.
$$

(c) For each $m \in \mathcal{M}'$, we can write $T_m = \psi \circ D^{-1} \circ \psi_m$, where

- The diffeomorphism $\psi_m$ is in $D^1_{1+\alpha}(C)$, its range contains $B(\Pi m, C_0^{1/2})$, and $\psi_m(\phi_m^{-1}(B(m, d))) \subset B(\Pi m, C_0^{1/2}/2)$.
- The matrix $D$ is block diagonal, of the form $D = (A_{\#} \ 0)$ with

$$
|Av| \geq C^{-1} \lambda_u(M) |v| \quad \text{and} \quad |Bv| \leq C \lambda_u(M) |v|.
$$

- The diffeomorphism $\psi$ is in $D^1_{1+\alpha}(C)$, its range contains $B(0, C_0^{1/2})$.

Note that (c) implies in particular that each $T_m$ sends stable leaves to stable leaves. Note also that if $C_0$ is large enough, then $\psi' \in \mathcal{F}(0, C^s)$ implies $(\psi')^{-1}(B(0, d)) \subset B(0, C_0^{1/2}/2)$. (Because $\|((\psi')^{-1})\|_{C^1} \leq C_{\#}$ by Lemma 2.8.)

Statements (b) and (c) are the main result of the lemma: (b) shows that the pullback of all the relevant charts $\phi_m$ can be glued together to form an admissible chart $\psi'$, while (c) gives an expression of $T_m$, that is, $T^{-1}$ in the charts $\phi_m, \psi'$, as the composition of two well controlled diffeomorphisms $\psi, \psi_m$, and a matrix $D$ with good hyperbolic properties. Statement (a), although an essential consequence of hyperbolicity, has a more technical nature: It is used in Step 2 of the proof of the lemma (when gluing foliations), and also later in the proof of Theorem 2.14. At the first reading, the reader can ignore the information on the ranges of $\psi$ and $\psi_m$ (but beware that they will be important in the proof of Theorem 2.14).

Remark 3.4. Composing with translations, we deduce a more general result from Lemma 3.3, replacing 0 by $\ell \in \mathbb{R}^d$, and allowing $T(\ell) \neq \ell$. Just replace $M$ by $DT(\ell)$, the projection $\Pi$ by $\Pi(x, y) = (x, y T(\ell))$, where $T(\ell) = (x T(\ell), y T(\ell))$, and assume that

$$
\|(T^{-1} \cdot + T(\ell)) - \ell \circ DT(\ell) - \text{id}\|_{C^{1+\alpha}} \leq \epsilon
$$

and that $DT(\ell)$ sends $C$ to $\tilde{C}$ compactly. One then uses the condition $B(m, d) \cap T(B(\ell, d)) \neq \emptyset$ to define $\mathcal{M}'$. Of course, $\psi'$ is then in $\mathcal{F}(\ell, C^s)$, equality (3.2) holds on $\phi_m^{-1}(B(m, d) \cap T(B(\ell, d)))$, and the range of $\psi$ contains $B(\ell, C_0^{1/2})$. Finally, we have $(\psi')^{-1}(B(\ell, d)) \subset B(\ell, C_0^{1/2}/2)$. 

Proof of Lemma 3.3. We shall write $\pi_1$ and $\pi_2$ for, respectively, the first and the second projection in $\mathbb{R}^d = \mathbb{R}^{d_u} \times \mathbb{R}^{d_v}$.

Step zero: Preparations. We shall write $C_\#, e_\#$ for a large, respectively small, constant, depending only on $C, \tilde{\mathcal{C}}$, and we shall write $C, \epsilon$ for constants depending on $C, \tilde{\mathcal{C}}$ and $C_0$.

The set $M(\mathbb{R}^{d_u} \times \{0\})$ is contained in $\tilde{\mathcal{C}}^a$, hence uniformly transverse to $\{0\} \times \mathbb{R}^{d_v}$. Therefore, it can be written as a graph $\{(x, Px)\}$ for some matrix $P$ with norm depending only on $\tilde{\mathcal{C}}$. Let $Q(x, y) = (x, y - Px)$, so that $QM$ sends $\mathbb{R}^{d_u} \times \{0\}$ to itself. In the same way, $M^{-1}(\{0\} \times \mathbb{R}^{d_v})$ is contained in $\mathcal{C}^a$, hence it is a graph $\{(P'y, y)\}$. Letting $Q'(x, y) = (x - P'y, y)$, the matrix $D = QM(Q')^{-1}$ leaves $\mathbb{R}^{d_u} \times \{0\}$ and $\{0\} \times \mathbb{R}^{d_v}$ invariant, i.e., it is block-diagonal, of the form $\left( \begin{array}{ll} A & 0 \\ 0 & B \end{array} \right)$, and moreover $|Av| \geq C^{-1}_\# |u|v|$ and $|Bv| \leq C_\# |\lambda_3|v|$ (since the matrices $Q$ and $Q'$, as well as their inverses, are uniformly bounded in terms of $C$ and $\tilde{\mathcal{C}}$).

We can readily prove assertion (a) of the lemma. Let $m \in \mathcal{M}'$, there exists $z \in B(m, d) \cap T(B(0, d))$. The set $QT(T(0, d)) = DQ'(T^{-1}M)^{-1}(B(0, d))$ is included in $\{(x, y) \mid |y| \leq C_\# \}$ for some constant $C_\#$ (the role of $Q$ is important here). Since $Qz \in QT(B(0, d))$, we obtain $|\pi_2(Qz)| \leq C_\#$. Since $|z - m| \leq d$, we also have $|Qz - Qm| \leq C_\#$, hence $|\pi_2(Qm)| \leq C_\#$ (for a different constant $C_\#$). Since $Qm - \Pi m = (x_m, \pi_2(Qm)) - (x_m, 0) = (0, \pi_2(Qm))$, we obtain

$$|Qm - \Pi m| \leq C_\#.$$  

Since the points $m \in \mathcal{M}'$ are far apart by assumption, the points $Qm$ for $m \in \mathcal{M}'$ are also far apart, and it follows that the points $\Pi m$ are also far apart. Increasing the distance between points in $\mathcal{M}'$, we can in particular ensure that $|\Pi m - \Pi m'| \geq C_0$ for any $m \neq m' \in \mathcal{M}'$, proving (a).

The strategy of the proof of the rest of the lemma is the following: We write

$$T^{-1} = T^{-1}M \cdot (Q')^{-1} \cdot D^{-1} \cdot Q.$$  

We shall start from the partial foliation given by the maps $\phi_m$ for $m \in \mathcal{M}$, apply $Q$ (Step 1) to obtain a new partial foliation at $Qm$, modify it via gluing (Step 2) to obtain a global foliation, and then push this foliation successively with $D^{-1}$ (Step 3), $(Q')^{-1}$ (Step 4), and $T^{-1}M$ (last step).

We shall use in this proof the spaces of local diffeomorphisms $\mathcal{D}(C_\#)$ and of matrix-valued functions $K(C_\#) = K^{\alpha, \beta}(C_\#)$ introduced in Appendix A. As in Remark A.6 of this appendix, we will write $K(C_\#, A)$ for the functions defined on a set $A$ and satisfying the inequalities defining $K(C_\#)$ ($A$ will sometimes be omitted when the domain of definition is obvious). The map $\phi_m$ belongs to $\mathcal{D}(C_\#)$ (see the proof of Lemma 2.8), and the matrix-valued function $D\phi_m$ belongs to $K(C_\#, B(m, C_0))$ (boundedness of $D\phi_m$ is proved in Lemma 2.8, while the Hölder-like properties are given by (2.10)–(2.12)).

First step: Pushing the foliations with $Q$. We formulate in detail the construction in this first step (a version of Lemma 3.5 will be used also in the last step, replacing $Q$ by $T^{-1}M$, while steps 2-3-4 are much simpler).

**Lemma 3.5.** (Notation as in Lemma 3.3 and Step 0 of its proof.) There exists a constant $C_\#$ such that, if $C_0$ is large enough, for any $m = (x_m, y_m) \in \mathcal{M}'$ there exist two maps $\phi_m^{(1)} : B(\Pi m, C_0^{1/2}) \to \mathbb{R}^d$ and $\Psi_m : B(m, C_0^{3/2}) \to \mathbb{R}^d$ such that

$$\phi_m^{(1)} \circ \Psi_m = Q \circ \phi_m \text{ on } \phi_m^{-1}(B(m, d)).$$  

Moreover, $\Psi_m$ is a diffeomorphism in $D_1^{1+\alpha}(C_\#)$ whose range contains $B(\Pi m, C_0^{1/2})$, and $\Psi_m(\phi_m^{-1}(B(m, d))) \subset B(\Pi m, C_0^{1/2}/2)$. Finally, $\phi_m^{(1)}(x, y) = (F_m^{(1)}(x, y), y)$ on
$B(\operatorname{Im}, C_0^{1/2})$, with $F_m^{(1)}$ a $C^1$ map so that $F_m^{(1)}(x,0) = x$ and $D F_m^{(1)}$ belongs to $\mathcal{K}(C_\#)$.

Note that if $\mathcal{E}$ is the foliation given by $\phi_m(x,y) = (F_m(x,y),y)$, then by definition $\phi_m^{(1)}$ sends the stable leaves of $\mathbb{R}^d$ to the foliation $Q\mathcal{E}$, i.e., $\phi_m^{(1)}$ is the standard parametrization of the foliation $Q\mathcal{E}$.

**Proof of Lemma 3.5.** Fix $m = (x_m, y_m) \in \mathcal{M}'$. The map $Q \circ \phi_m$ does not qualify as $\phi_m^{(1)}$ for two reasons. First, $\pi_2 \circ Q \circ \phi_m(x,y)$ is generally not equal to $y$. Second, $\pi_1 \circ Q \circ \phi_m(x,0)$ is generally not equal to $x$. We shall use two maps $\Gamma^{(0)}$ and $\Gamma^{(1)}$ (sending stable leaves to stable leaves) to compensate for these two problems. The map $\Gamma^{(0)}$ will have the form $\Gamma^{(0)}(x,y) = (x, G(x,y))$ where for fixed $x$, the map $y \mapsto G(x,y)$ will be a diffeomorphism of the vertical leaf $\{x\} \times \mathbb{R}^d$, so that $\pi_2 \circ Q \circ \phi_m \circ \Gamma^{(0)}(x,y) = y$. In particular, $Q \circ \phi_m \circ \Gamma^{(0)}(x,0)$ is of the form $(L^{(1)}(x),0)$, for some map $L^{(1)}$. Choosing $\Gamma^{(1)}(x,y) = (L^{(1)})^{-1}(x,y)$ solves our second problem: the map

$$
\phi_m^{(1)} := Q \circ \phi_m \circ \Gamma^{(0)} \circ \Gamma^{(1)}
$$

satisfies both $\pi_2 \circ \phi_m^{(1)}(x,y) = y$ and $\pi_1 \circ \phi_m^{(1)}(x,0) = x$, as desired. Then, the map

$$
\Psi_m = (\Gamma^{(0)} \circ \Gamma^{(1)})^{-1}
$$

sends stable leaves to stable leaves and $Q \circ \phi_m = \phi_m^{(1)} \circ \Psi_m$.

We shall now be more precise, justifying the existence of the maps mentioned above, and estimating their domain of definition, their range and their smoothness.

The map $\Gamma^{(0)}$. For fixed $x$, the map $y \mapsto G(x,y)$ should satisfy $\pi_2 \circ Q \circ \phi_m(x,G(x,y)) = y$, i.e., it should be the inverse to the map

$$
L_x : y \mapsto \pi_2 \circ Q \circ \phi_m(x,y) = y - PF_m(x,y),
$$

where we denote $\phi_m(x,y) = (F_m(x,y),y)$. We claim that this map is invertible onto its image, and that there exists $\epsilon_m^0 > 0$ such that

$$
|L_x(y') - L_x(y)| \geq \epsilon_m^0 |y' - y|, \quad \forall x \in B(x_m, C_0), \quad \forall y, y' \in B(y_m, C_0).
$$

Indeed, fix $x \in B(x_m, C_0)$ and let $w = y' - y$. Writing $F(y) = F_m(x,y)$, we have

$$
L_x(y') - L_x(y) = w - \int_{x=0}^1 \partial_y F(y + tw)w\, dt.
$$

Each vector $(\partial_y F(y + tw),w)$ belongs to $\tilde{C}^s$. Since this cone is convexly transverse to $\mathbb{R}^{d_x} \times \{0\}$,

$$
v_1 := \left( \int_{x=0}^1 \partial_y F(y + tw)w\, dt, w \right) \in \tilde{C}^s,
$$

On the other hand, since the graph of $P$ is included in $\tilde{C}^u$, $v_2 := (\int_{x=0}^1 \partial_y F(y + tw)w\, dt, P \int_{x=0}^1 \partial_y F(y + tw)w\, dt)$ belongs to $\tilde{C}^u$. Let $\epsilon_m^0 > 0$ be such that $B(v, \epsilon_m^0 |v|) \cap \tilde{C}^s = \emptyset$ for any $v \in \tilde{C}^s - \{0\}$. Since $v_1 \in \tilde{C}^s$ and $v_2 \in \tilde{C}^u$, we get $|v_1 - v_2| \geq \epsilon_m^0 |v_1|$. As $v_1$ and $v_2$ have the same first component, this gives $|\pi_2(v_1) - \pi_2(v_2)| \geq \epsilon_m^0 |v_1|$, i.e.,

$$
|w - \int_{x=0}^1 \partial_y F(y + tw)w\, dt| \geq \epsilon_m^0 |w|,
$$

which implies (3.6) by (3.7).

The map $\Lambda^{(0)} : (x,y) \mapsto (x, L_x(y))$ is well defined on $B(m, C_0)$, its derivative is bounded by a constant $C_\#$, and its second component satisfies (3.6). Lemma A.1 (with $x$ and $y$ exchanged) shows that $\Lambda^{(0)} \in D(C_\#)$ for some constant $C_\#$. In particular, $\Lambda^{(0)}$ admits an inverse $\Gamma^{(0)}$, which also belongs to $D(C_\#)$. 

By Lemma A.2, the range of $\Lambda(0)$ (which coincides with the domain of definition of $\Gamma^{(0)}$) contains the ball $B(\Lambda^{(0)}(m), C_0/C_\#)$. Moreover, $\Lambda^{(0)}(m) = Qm$. By (3.3), we have $|Qm - \Pi m| \leq C_\#$, hence the domain of definition of $\Gamma^{(0)}$ contains $B(\Pi m, C_0/C_\# - C_\#')$. If $C_0$ is large enough, this contains $B(\Pi m, C_0^{2/3})$.

The map $\Gamma^{(1)}$. Consider $\phi^{(0)}_m := Q \circ \phi_m \circ \Gamma^{(0)}$. It is a composition of maps in $\mathcal{D}(C_\#)$, hence it also belongs to $\mathcal{D}(C_\#)$. Moreover, its restriction to $\mathbb{R}^d \times \{0\}$ has the form $(x, 0) \mapsto (L^{(1)}(x), 0)$. It follows that the map $L^{(1)}$ also belongs to $\mathcal{D}(C_\#)$.

In particular, it is invertible, and we may define $\Gamma^{(1)}(x, y) = ((L^{(1)})^{-1}(x), y)$. This map belongs to $\mathcal{D}(C_\#)$. By construction, $\phi^{(1)}_m := Q \circ \phi_m \circ \Gamma^{(0)} \circ \Gamma^{(1)}$ can be written as $(F^{(1)}_m(x, y), y)$ with $F^{(1)}_m(x, 0) = x$.

We have $\phi^{(0)}_m(Qm) = Qm$. Since $|\Pi m - Qm| \leq C_\#$ by (3.3), and $\phi^{(0)}_m$ is Lipschitz, we obtain $|\phi^{(0)}_m(\Pi m) - \Pi m| \leq C_\#$, i.e., $L^{(1)}(x_m) - x_m \leq C_\#$. Since $L^{(1)} \in \mathcal{D}(C_\#)$, Lemma A.2 shows that $L^{(1)}(B(x_m, C_0^{2/3}))$ contains the ball $B(x_m, C_0^{2/3}/C_\# - C_\#')$. Therefore, it contains the ball $B(x_m, C_0^{1/2})$ if $C_0$ is large enough. Hence, the domain of definition of the map $\Gamma^{(1)}$ contains $B(\Pi m, C_0^{1/2})$. This shows that $\phi^{(1)}_m$ is defined on $B(\Pi m, C_0^{1/2})$.

The map $\Psi_m$. We can now define $\Psi_m = (\Gamma^{(0)} \circ \Gamma^{(1)})^{-1} = (L^{(1)}(x), L_x(y))$, so that $Q \circ \phi_m = \phi^{(1)}_m \circ \Psi_m$. We have seen that $\Psi_m \in \mathcal{D}(C_\#)$, hence $D\Psi_m$ and $D\Psi_m^{-1}$ are uniformly bounded. To show that $\Psi_m \in D_{\Gamma^{(1)}}(C_\#)$, we should check that $|D\Psi_m(x, y) - D\Psi_m(x', y')| \leq C|y - y'|^\alpha$. This follows directly from the construction and the corresponding inequality (2.10) for $DF_m$. Finally, since $\Psi_m \in \mathcal{D}(C_\#)$,

$$\Psi_m(\phi^{-1}_m(B(m, d))) \subset \Psi_m(B(m, C_\#)) \subset B(\Psi_m(m), C_\#).$$

Since $Qm = \phi^{(1)}_m(\Psi_m(m))$ and $\Pi m = \phi^{(1)}_m(\Pi m)$, we get $|\Psi_m(m) - \Pi m| \leq C_\# |Qm - \Pi m| \leq C_\#$ by (3.3). Therefore, $\Psi_m(\phi^{-1}_m(B(m, d))) \subset B(\Pi m, C_\#)$, and this last set is included in $B(\Pi m, C_0^{1/2}/2)$ if $C_0$ is large enough.

The regularity of $DF^{(1)}_m$. To finish the proof, we should prove that $DF^{(1)}_m$ satisfies the bounds defining $\mathcal{K}(C_\#)$, for some constant $C_\#$ independent of $C_0$. Since $\phi^{(1)}_m = Q \circ \phi_m \circ \Gamma^{(0)} \circ \Gamma^{(1)}$, we have

$$DF^{(1)}_m = (DQ \circ \phi_m \circ \Gamma^{(0)} \circ \Gamma^{(1)}) \cdot (D\phi_m \circ \Gamma^{(0)} \circ \Gamma^{(1)}) \cdot (D\Gamma^{(0)} \circ \Gamma^{(1)}) \cdot D\Gamma^{(1)}.$$

Since $\mathcal{K}$ is invariant under multiplication (Proposition A.4), and under composition by Lipschitz maps sending stable leaves to stable leaves (Proposition A.5), it is sufficient to show that $D\phi_m$, $D\Gamma^{(0)}$, and $D\Gamma^{(1)}$ all satisfy the bounds defining $\mathcal{K}(C_\#)$. For $D\phi_m$, this follows from our assumptions (note that this is where (2.11)–(2.12) are used).

Since $\Gamma^{(0)} = (\Lambda^{(0)})^{-1}$, we have $D\Gamma^{(0)} = (D\Lambda^{(0)})^{-1} \circ \Gamma^{(0)}$. Since $D\Lambda^{(0)}$ is expressed in terms of $DF_m$, it belongs to $\mathcal{K}$. As $\mathcal{K}$ is invariant under inversion (Proposition A.4) and composition, we obtain $D\Gamma^{(0)} \in \mathcal{K}(C_\#)$.

Since $D\phi^{(1)}_m(x, 0) = id$, it follows from (3.9) that, on the set $\{(x, 0)\}$, $D\Gamma^{(1)}$ is the inverse of the restriction of a function in $\mathcal{K}$, and in particular $D\Gamma^{(1)}(x, 0)$ is a $\beta$-Hölder continuous function of $x$, by (A.7). Since $D\Gamma^{(1)}(x, y)$ only depends on $x$, it follows that $D\Gamma^{(1)}$ belongs to $\mathcal{K}$. This concludes the proof of Lemma 3.5. □

We return to the proof of Lemma 3.3:

Second step: Gluing the foliations $\phi^{(1)}_m$ together.

Let $\gamma(x, y)$ be a $C^\infty$ function equal to 1 on the ball $B(C_0^{1/2}/2)$, vanishing outside of $B(C_0^{1/2})$. Let $\phi^{(1)}_m(x, y) = (F^{(1)}_m(x, y), y)$ be a foliation defined by Lemma 3.5,
and put
\begin{equation}
\phi_m^{(2)}(x, y) = (\gamma(x - x_m, y)(F_{m}^{(1)}(x, y) - x) + x, y).
\end{equation}

Then \( \phi_m^{(2)} \) defines a foliation on the ball of radius \( C_0^{1/2} \) around \( \Pi_m \), coinciding with \( \phi_m^{(1)} \) on \( B(\Pi_m, C_0^{1/2}/2) \), and \( \phi_m^{(2)} \) is equal to the identity on the boundary of \( B(\Pi_m, C_0^{1/2}) \). By construction, \( \phi_m^{(2)}(x, y) = (F_{m}^{(2)}(x, y), y) \) with \( F_{m}^{(2)}(x, 0) = x \). Moreover, \( DF_{m}^{(2)} \) is expressed in terms of \( \gamma, D\gamma, F_{m}^{(1)} \), and \( DF_{m}^{(1)} \). All those functions belong to \( \mathcal{K}(C_{\#}) \) (the first three functions are Lipschitz and bounded, hence in \( \mathcal{K}(C_{\#}) \), while we proved in Lemma 3.5 that \( DF_{m}^{(1)} \in \mathcal{K}(C_{\#}) \)). Therefore, \( DF_{m}^{(2)} \in \mathcal{K}(C_{\#}) \) by Proposition A.4.

We proved in (a) that the balls \( B(\Pi_m, C_0^{1/2}) \) for \( m \in \mathcal{M}' \) are disjoint, therefore all those foliations can be glued together (with the trivial vertical foliation outside of \( \bigcup_{m \in \mathcal{M}', B(\Pi_m, C_0^{1/2}))} \), to get a single foliation parameterized by \( \phi^{(2)} : \mathbb{R}^d \to \mathbb{R}^d \). We emphasize that this new foliation is not necessarily contained in the cone \( Q(\mathcal{C}) \), since the function \( \gamma \) contributes to the derivative of \( \phi^{(2)} \). Nevertheless, it is uniformly transverse to the direction \( \mathbb{R}^d \times \{0\} \), and this will be sufficient for our purposes. Let us write \( \phi^{(2)}(x, y) = (F^{(2)}(x, y), y) \), where \( F^{(2)} \) coincides everywhere with a function \( F_{m}^{(2)} \) or with the function \( (x, y) \mapsto x \). Since all the derivatives of those functions belong to \( \mathcal{K}(C_{\#}) \), it follows that \( DF^{(2)} \in \mathcal{K}(C_2) \), for some constant \( C_2 \) (worse than \( C_{\#} \) due to the gluing).

**Third step: Pushing the foliation \( \phi^{(2)} \) with \( D^{-1} \).** This step is very simple, although this is where (3.1) is needed: Define a new foliation by
\begin{equation}
F^{(3)}(x, y) = A^{-1}F^{(2)}(Ax, By), 
\phi^{(3)}(x, y) = (F^{(3)}(x, y), y),
\end{equation}
so that \( D^{-1}\phi^{(3)} = \phi^{(3)}D^{-1} \). The map \( F^{(3)} \) satisfies \( F^{(3)}(x, 0) = x \). Moreover
\begin{equation}
\partial_x F^{(3)}(x, y) = A^{-1}(\partial_x F^{(2)})(Ax, By)A, \quad \partial_y F^{(3)}(x, y) = A^{-1}(\partial_y F^{(2)})(Ax, By)B.
\end{equation}

In particular, if \( |A^{-1}| \) and \( |B| \) are small enough (which can be ensured by increasing \( C \) in (3.1)), we can make \( \partial_y F^{(3)} \) arbitrarily small. Since \( |B| \leq 1 \leq |A| \), it also follows that
\begin{equation}
|DF^{(3)}(x, y) - DF^{(3)}(x, y')| \leq |A^{-1}||A||DF^{(2)}(Ax, By) - DF^{(2)}(Ax, By')|
\leq |A^{-1}||A||C_2|By - By'|^\alpha \leq |A^{-1}||A||C_2|B^\alpha|y - y'|^\alpha.
\end{equation}

In the same way,
\begin{equation}
|DF^{(3)}(x, y) - DF^{(3)}(x', y') - DF^{(3)}(x', y) + DF^{(3)}(x', y')| \leq |A^{-1}||A||DF^{(2)}(Ax, By) - DF^{(3)}(Ax, By') - DF^{(3)}(Ax', By')|
\leq |A^{-1}||A||C_2|Ax - Ax'|^\beta|By - By'|^{\alpha - \beta}
\leq |A^{-1}||A||C_2|A^\beta|B^{1/2}|y - y'|^{\alpha - \beta/4C_2^2}.
\end{equation}

If the bunching constant \( \epsilon \) in (3.1) is small enough, we can ensure that the two last equations are bounded, respectively, by \( (|y - y'|/2C_2)^\alpha \) and \( |x - x'|^\beta |y - y'|^{\alpha - \beta}/(4C_2^2) \), i.e., the map \( F^{(3)} \) satisfies the requirements (2.10) and (2.12) for admissible foliations, with slightly better constants.

Taking \( y' = 0 \) in (3.13), we obtain
\begin{equation}
|DF^{(3)}(x, y) - DF^{(3)}(x', y)| \leq |x - x'|^\beta |y|^{\alpha - \beta}/(4C_2^2) + |DF^{(3)}(x, 0) - DF^{(3)}(x', 0)|.
\end{equation}
Moreover, \( \partial_y F(3)(x,0) = \partial_x F(3)(x',0) = \text{id} \), so that
\[
|DF(3)(x,0) - DF(3)(x',0)| = |\partial_y F(3)(x,0) - \partial_y F(3)(x',0) | \\
\leq |A^{-1}| |B||\partial_y F(2)(Ax,0) - \partial_y F(2)(Ax',0)| \\
\leq |A^{-1}| |B| |C_2| |Ax - Ax'|^\beta \leq |A^{-1}| |B| |C_2| |x - x'|^\beta.
\]

The quantity \( |A^{-1}| |B| |A|^{\beta} \) is bounded by \( C_\# \lambda_{x}^{-1} \lambda_{s} \Lambda_{0}^{\beta} \). Choosing \( \epsilon \) small enough in (3.1), it can be made arbitrarily small. For \( |y| \leq C_0^{\beta} \), this yields
\[
|DF(3)(x,y) - DF(3)(x',y)| \leq |x - x'|^\beta / 2,
\]
which is a small reinforcement of (2.11).

Fourth step: Pushing the foliation \( \phi^{(3)} \) with \( (Q')^{-1} \). Define a map \( F^{(4)}(x,y) = F^{(3)}(x,y) + P(y) \), and let \( \phi^{(4)}(x,y) = (F^{(4)}(x,y),y) \). The corresponding foliation is the image of \( \phi^{(3)} \) under \( (Q')^{-1} \). Let us fix a cone \( C_1^\alpha \) which sits compactly between \( C_0^\beta \) and \( C^\ast \). Since the graph \( \{(P,y,y)\} \) is contained in \( C_0^\beta \), the foliation \( F^{(4)} \) is contained in \( C_1^\alpha \) if \( \partial_y F^{(3)} \) is everywhere small enough. Moreover, the bounds of the previous step concerning \( DF^{(3)} \) directly translate into the following bounds for \( DF^{(4)} \), for all \( x, x' \in \mathbb{R}^d \) and all \( y, y' \in B(0,C_0^\beta) \):
\[
|DF^{(4)}(x,y) - DF^{(4)}(x,y')| \leq \left( \frac{|y - y'|}{2C_0^\beta} \right)^{\alpha}, \tag{3.15}
\]
\[
|DF^{(4)}(x,y) - DF^{(4)}(x',y')| \leq |x - x'|^{\beta / 2}, \tag{3.16}
\]
\[
|DF^{(4)}(x,y) - DF^{(4)}(x',y') - DF^{(4)}(x',y') + DF^{(4)}(x',y')| \\
\leq |x - x'|^{\beta / 2} |y - y'|^{(\alpha - \beta) / (2C_0^\beta)}. \tag{3.17}
\]

In particular, since \( \partial_y F^{(4)}(x,0) = \text{id} \), the bound (3.15) implies that \( \partial_y F^{(4)} \) is invertible (with bounded inverse) on a ball of radius of the order of \( C_0^\beta \).

Last step: Pushing the foliation \( \phi^{(4)} \) with \( T^{-1}M \). Let \( \phi' \) be obtained by pushing the foliation \( \phi^{(4)} \) with the map \( T^{-1}M \). Using arguments similar to those in the proof of Lemma 3.5, one can check that \( (T^{-1}M) \circ \phi^{(4)} = \phi' \circ \Psi \) for some map \( \Psi \in D_{1+\alpha}^1 \), whose differential is everywhere close to the identity and whose range contains \( B(0,C_0^{\beta/2}) \). The last remark in Step 4 implies that \( \phi' \) is defined on \( B(0,C_0^\beta) \).

Letting \( F' \) be the map corresponding to \( \phi' \), since \( \partial_y F'(w, w) \) takes its values in the cone \( C_1^\alpha \), it follows that \( \partial_y F'(w, w) \) lies in the cone \( C^\ast \) if \( T^{-1}M \) is close enough to the identity. Hence, the foliation defined by \( \phi' \) is contained in \( C^\ast \). Moreover, it follows from the estimates on \( F^{(4)} \) that \( F' \) satisfies the requirements (2.10)–(2.12) hence \( \phi' \in F(0,C^\ast) \). This concludes the proof of Lemma 3.3. \( \square \)

Remark 3.6. An inspection of the proof of Lemma 3.3 shows that one can obtain stronger conclusions: For any \( C' > 0 \), one can ensure that the final chart \( \phi' \) is defined on a ball of radius \( C' \), and satisfies \( |D\phi'(x,y) - D\phi(x,y')| \leq (|y - y'|/C')^\alpha \), as follows. If the bunching and hyperbolicity conditions in (3.1) are large enough, the third step of the proof yields a chart \( \phi^{(3)} \) with \( |DF^{(3)}(x,y) - DF^{(3)}(x,y')| \leq \delta|y - y'|^\alpha \) for arbitrarily small \( \delta > 0 \). Hence, in the inequality (3.15) regarding the map \( F^{(4)} \) (which is defined on \( \mathbb{R}^d \)), the constant \( 2C_0^\beta \) can be replaced with an arbitrarily large constant, allowing an arbitrarily large domain of definition for \( \phi' \). The same observation holds for (3.16) and (3.17). This remark is the key to the proof of Proposition 2.15.

\[ \text{In fact, the analogue of (3.6) to obtain invertibility of } DA^{(0)} \text{ there is easier since } T^{-1}M \text{ is close to the identity in } C^{1+\alpha} \text{.} \]
4. Results on the local spaces $\mathcal{H}^t_{p,s}$.

4.1. Basic facts on the local spaces $\mathcal{H}^t_{p,s}$. We start with reminders from [BG09].

The proof of Lemma 22 from [BG09] implies the following:

**Lemma 4.1.** Let $t > 0$, $s < 0$ and $\tilde{\alpha} > 0$ be real numbers with $t + |s| < \tilde{\alpha}$. For any $p \in (1, \infty)$, there exists a constant $C_\#$ such that for any $C^\infty$ function $g : \mathbb{R}^d \rightarrow \mathbb{C}$,

$$\|g \cdot w\|_{\mathcal{H}^t_{p,s}} \leq C_\# \|g\|_{C^\infty} \|w\|_{\mathcal{H}^t_{p,s}}.$$ 

The following extension of a classical result of Strichartz (see [BG09, Lemma 23]) is the key to our results.

**Lemma 4.2.** Let $1 < p < \infty$ and $1/p - 1 < s \leq 0 < t < 1/p$. Let $e_1, \ldots, e_d$ be a basis of $\mathbb{R}^d$, such that $e_{d+1}, \ldots, e_d$ form a basis of $\{0\} \times \mathbb{R}^{d-1}$. There exists a constant $C_\#$ (depending only on $p, s, t$ and $e_1, \ldots, e_d$) so that, for any subsets $U_1, \ldots, U_n$ of $\mathbb{R}^d$ whose intersection with almost every line directed by a vector $e_i$ has at most $L$ connected components,

$$\left\|\bigcap_i U_i w\right\|_{\mathcal{H}^t_{p,s}} \leq C_\# n L \|w\|_{\mathcal{H}^t_{p,s}}.$$ 

**Proof.** If $A$ and $B$ are open subsets of $\mathbb{R}$, respectively with $a$ and $b$ connected components, then $A \cap B$ has at most $a + b - 1$ connected components. Therefore, under the assumptions of the lemma, the set $\bigcap U_i$ intersects almost any line directed by a vector $e_i$ along at most $L + (n - 1)(L - 1) \leq n L$ connected components. The result then follows from Lemma 23 of [BG09] and a linear change of coordinates. \qed

The following is essentially Lemma 28 in [BG09].

**Lemma 4.3 (Localization principle).** Let $\mathbb{K}$ be a compact subset of $\mathbb{R}^d$. For each $m \in \mathbb{Z}^d$, consider a function $\eta_m$ supported in $m + \mathbb{K}$, with uniformly bounded $C^1$ norm. For any $p \in (1, \infty)$ and $t, s \in \mathbb{R}$ with $|t| + |s| < 1$, there exists $C_\# > 0$ so that for each $w \in \mathcal{H}^t_{p,s}$

$$\left(\sum_{m \in \mathbb{Z}^d} \|\eta_m w\|_{\mathcal{H}^t_{p,s}}^p\right)^{1/p} \leq C_\# \|w\|_{\mathcal{H}^t_{p,s}}.$$ 

**Proof.** Consider a compactly supported $C^\infty$ function $\gamma$, equal to 1 on $\mathbb{K}$, and write $\gamma_m(z) = \gamma(z - m)$. Then $\eta_m = \eta_m \gamma_m$, and

$$\|\eta_m w\|_{\mathcal{H}^t_{p,s}}^p = \|\eta_m \gamma_m w\|_{\mathcal{H}^t_{p,s}}^p \leq C_\# \|\gamma_m w\|_{\mathcal{H}^t_{p,s}}^p$$

by Lemma 4.1. The result follows by applying [BG09, Lemma 28]. \qed

For any real number $t$ and any $1 < p < \infty$, we set $H^t_p(\mathbb{R})$ to be the Sobolev-Triebel space defined as the distributions that have finite $H^t_p(\mathbb{R}^d)$ norm in any (fixed) smooth coordinate system.

As usual, a compact imbedding statement à la Arzelà-Ascoli will be used (recall that $X_0$ is compact):

**Lemma 4.4.** Let $s < 0 < t$ with $t + |s| < 1$, and let $1 < p < \infty$. Assume that $t - |s| > -\beta$. Then the space $\mathcal{H}^t_{p,s}(\mathbb{R})$ is continuously embedded in $H^t_{p, |s|}(X_0)$. In addition, we have the continuous embeddings

$$\mathcal{H}^t_{p,s} \subset \mathcal{H}^{t', s'}_{p,s} \text{ if } t' \leq t \text{ and } s' \leq s.$$ 

Moreover, this inclusion is compact if $t' < t$. 

Proof. Before proving the lemma, we start with a functional analytic preliminary, required because \( t - |s| \) will be strictly negative in our application of the lemma. If \( 1/p + 1/p' = 1 \) for \( 1 < p, p' < \infty \) and \( r > 0 \), then classical duality results (see e.g. [BG09, Lemma 20] and references therein) yield \((H_p^t)^* = H_{p'}^{-r} \). If \( G \) is a diffeomorphism of \( \mathbb{R}^d \) then the dual operator \( L^* \) on \( H_p^t \) to \( L(p') = w' \circ G \) is \( w \mapsto |\det DG^{-1}| w \circ G^{-1} \). For \( r \in [0,1] \), \( H_p^t \) is invariant under the composition by a \( C^1 \) diffeomorphism \( G \) (since this is the case of \( H_0^p = L_p^p, \) and \( H_1^1 \)). By duality, \( H_{p'}^{-r} \) is invariant by \( w \mapsto |\det DG^{-1}| \cdot w \circ G^{-1} \). Therefore, Lemma 4.1 shows that \( H_{p'}^{-r} \) is invariant under the composition with diffeomorphisms whose Jacobian is \( C^\beta \) for some \( \beta > r \).

We now turn to the proof of the lemma. In any admissible chart, the continuous embedding claim (4.1) follows from the definitions and properties of Triebel spaces, taking the supremum over all admissible charts.

Consider now \( s' \leq s \) and \( t' < t \). Fix also \( t_0 < t \) with \( t_0 - |s| > -\beta \). Since \( H_{p,s}^t \) is included in \( H_{p,-|s|}^{t_0} \), it follows by taking the supremum over the admissible charts that \( H_{p,s}^t \) is included in \( H_{p,-|s|}^{t_0} \). Moreover, for any admissible charts \( \phi_1, \phi_2 \in \mathcal{F}(\zeta) \) for some \( \zeta \) (recall (2.17)), the change of coordinates \( \phi_2 \circ \phi_1^{-1} \) is \( C^1 \) and has a (uniformly) \( C^\beta \) Jacobian. It follows from the functional analytic preliminary that changing the system \( \Phi \) of charts in the definition of the \( H_{p,s}^t \)-norm gives equivalent norms. Therefore, \( H_{p,s}^{t_0} \) is isomorphic to the Triebel space \( H_{p,s}^{t_0} \). Since the inclusion of \( H_{p,s}^{t_0} \) in \( H_{p,s}^{t_0} \) is compact, it follows that the inclusion \( \Phi^p_s(R) \rightarrow \Phi^p_s(R) \) is also compact.

Consider now a sequence \( \omega_n \in \Phi^p_s(R) \), with norms bounded by 1. To prove that the inclusion of \( \Phi^p_s \) in \( \Phi^p_s \) is compact, it is sufficient to show that, for any \( \epsilon \), there exists a subsequence of \( \omega_n \) along which

\[
\limsup \|\omega_n - \omega_m\|_{\Phi^p_s(R)} \leq 2\epsilon.
\]

We can assume without loss of generality that \( \omega_n \) converges in \( \Phi^p_s(R) \). Let \( C(\epsilon) \) be such that any distribution \( \omega \) on \( \mathbb{R}^d \) satisfies

\[
\|\omega\|_{\Phi^p_s} \leq \epsilon \|\omega\|_{\Phi^p_s} + C(\epsilon) \|\omega\|_{\Phi^p_{s'}},
\]

To prove that such a constant \( C(\epsilon) \) exists, let us note that the kernel \( a_{c,s'} \) defining the \( \Phi^p_s \)-norm is bounded by \( a_{c,s} \) outside of a compact set, where it is bounded by \( C(\epsilon) a_{c,s} \) if \( C(\epsilon) \) is large enough. The result follows from the Marcinkiewicz multiplier theorem (see e.g. [BG09, Theorem 21] or [Tri77, Theorem 2.4.2]).

Taking the supremum of the equation (4.3) over the admissible charts, we obtain

\[
\|\omega_n - \omega_m\|_{\Phi^p_s(R)} \leq \epsilon \|\omega_n - \omega_m\|_{\Phi^p_s(R)} + C(\epsilon) \|\omega_n - \omega_m\|_{\Phi^p_{s'}(R)}.
\]

Since the quantity \(\|\omega_n - \omega_m\|_{\Phi^p_{s'}(R)} \) converges to 0 when \( n, m \to \infty \), this proves (4.2).

The following lemma on partitions of unity is Lemma 32 from [BG09]:

**Lemma 4.5.** Let \( t \) and \( s \) be arbitrary real numbers. There exists a constant \( C_{\#} \) such that, for any distributions \( v_1, \ldots, v_l \) with compact support in \( \mathbb{R}^d \), belonging to \( H_{p,s}^t \), there exists a constant \( C \) depending only on the supports of the distributions \( v_i \) with

\[
\left| \sum_{i=1}^l v_i \right|_{H_{p,s}^t} \leq C_{\#} m^{p-1} \sum_{i=1}^l \|v_i\|_{H_{p,s}^t} + C \sum_{i=1}^l \|v_i\|_{H_{p,s}^{t-1,s}}.
\]
where \( m \) is the intersection multiplicity of the supports of the \( v_i \)'s, i.e., \( m = \sup_{x \in \mathbb{R}} \text{Card}\{t \mid x \in \text{supp}(v_i)\} \).

### 4.2. The effect of composition on the local space \( H^{s}\( \lambda \) \).

In view of Theorem 2.5, we describe how the local spaces \( H^{s}\( \lambda \) \) behave under composition with hyperbolic matrices and appropriate maps preserving the stable leaves.

The following lemma is a particular case of [BG09, Lemma 25].

**Lemma 4.6.** For all \( s < 0 < t < 1 \), \( |s| > 0 \), and every \( t' < t \) there exists a constant \( C_{\#} \) (depending only on \( s, p, t' \)) such that \( |Av| \leq \lambda_n|v| \) and \( |Bv| \leq \lambda_s|v| \) for \( \lambda_n > 1 \) and \( \lambda_s < 1 \). Then there exists a constant \( C \) such that, for all \( w \in L^{s}\),

\[
\|w \circ D^{-1}\|_{H^{s}\( \lambda \)} \leq C_{\#} \int |\det D_{\Psi}| \max(\lambda_n^{-s}, \lambda_s^{-(t+s)}) \|w\|_{H^{s}\( \lambda \)} + C\|w\|_{H^{s}\( \lambda \)}.
\]

Adapting the second part of the proof of [BG09, Lemma 25] gives:

**Lemma 4.7.** Let \( C > 0 \), and let \( -\alpha < s < 0 < t < 1 \) with \( C \int |Av| \leq \lambda_n|v| \) and \( \lambda_n > 1 \) and \( \lambda_s < 1 \). Then there exists a constant \( C' \) so that for any \( \Psi \in D_{1+\alpha}(C) \) whose range contains a ball \( B(z, C^{1/2}_{\Psi}) \), and for any distribution \( v \in H^{s}\( \lambda \) \) supported in \( B(z, C^{1/2}_{\Psi}) \), the composition \( v \circ \Psi \) is well defined, and

\[
\|v \circ \Psi\|_{H^{s}\( \lambda \)} \leq C'\|v\|_{H^{s}\( \lambda \)}.
\]

**Proof.** Without loss of generality, we may assume \( z = \Psi^{-1}(z) = 0 \). Let \( \gamma \) be a \( C^\infty \) function equal to 1 on \( B(0, C^{1/2}_{\Psi}) \) and vanishing outside of \( B(0, C^{1/2}_{\Psi}) \). We want to show that the operator \( \mathcal{M} : v \mapsto (\gamma v) \circ \Psi \) is bounded by \( C' \) as an operator from \( H^{s}\( \lambda \) \) to itself. By interpolation, it is sufficient to prove this statement for \( H^{1,0} \), for \( L^{p} \), and for \( H^{0,-\alpha} \). This is done in the second step of the proof of Lemma 25 in [BG09] – the result there is formulated for \( C^{1+\alpha} \) diffeomorphisms, but a glance at the proof there indicates that the \( C^{0} \) regularity of the Jacobian is only used along the stable leaves, in the argument for \( H^{0,-\alpha} \), and the definition of \( D_{1+\alpha}(C) \) ensures that the Jacobian is indeed regular along stable leaves.

### 5. Proof of the main theorem on piecewise cone hyperbolic maps

In this section, we prove Theorem 2.14 and Proposition 2.15.

We may fix once and for all a constant \( C_0 > 10 \) large enough so that the assumptions of Lemma 3.3 are satisfied for the finite set \( C_{i,j} \) of extended cones chosen in Section 2.3. Denote by \( C_{i} \) and \( \epsilon_{i} \) the resulting constants \( C \) and \( \epsilon \) given by this lemma, fixed once and for all. In the following arguments, we shall denote by \( C_{\#} \) and \( \epsilon_{\#} \) constants that may vary from one line to the other, but do not depend on \( n \).

The following lemma implies Theorem 2.14 since the inclusion of \( H^{s}_{\lambda} \) into \( H^{s}_{\lambda} \) is compact for \( s < 0 < t \) if \( t' < t \), and \( t + |s| < 1 \), \( t - |s| > -\beta \), by Lemma 4.4.

**Lemma 5.1.** Let \( \alpha, T, g, p \) be as in Theorem 2.5 and let \( 1/p - 1 < s < 0 < t < 1/p \), with \( \alpha |s| + t < \alpha \). For any \( t' < t \) there is \( C_{\#} \) so that, for any fixed \( n \), if \( R \) is large enough, then there exists \( C_{n} \) so that

\[
\|P_{n}^{\alpha}\|_{H^{s} \cap (R)} \leq C_n \|\omega\|_{H^{s} \cap (R)} + C_{\#} n^{p} D_{n}^{c} D_{n}^{r-1} \left( \left\| \det D T^{\alpha} \max(\lambda_n^{-n}, \lambda_s^{-(s+t)}) p|g_n| p \right\|_{L^{\infty}} \left\| \omega\|_{H^{s} \cap (R)} \right) .
\]

**Proof of Lemma 5.1.** To simplify notation, we write \( x \leq x \) if \( x \leq y \) up to compact terms, i.e., terms which are controlled by \( \|\omega\|_{H^{s}_{\lambda} \cap (R)} \) for some \( t' < t \). Note that if \( t'' < t \) is such that \( t'' < t' \), then an upper bound in terms of \( t'' \) trivially implies the
up to a small neighborhood $\tilde{O}_i$ of $\overline{O}_i$ such that $T_i$ admits an extension to $\tilde{O}_i$ with the same hyperbolicity properties as the original $T_i$. Reducing these sets if necessary, we can ensure that their intersection multiplicity is bounded by $D^e_n$, and that the intersection multiplicity of the sets $T_i\tilde{O}_i$ is bounded by $D^e_n$.

For $\zeta = (i,j,m) \in Z(R)$, we let us write

$$A(\zeta) = A(\zeta, R) = (\kappa^R_i)^{-1}(B(m,d)) \subset X.$$  

The set $A(\zeta)$ is a neighborhood of $q_\zeta$, of diameter bounded by $C_\# R^{-1}$, and containing the support of $\rho_\zeta$.

Let us fix some system of charts $\Phi$ as in the Definition 2.12 of the $H^s_p(R)$-norm. We want to estimate $\|L^p_\gamma \omega\|_{\Phi,R}$.

First step. The sets \{ $T_i(O_i) \mid i \in I^n$ \} have intersection multiplicity at most $D^e_n$. Writing $L^p_\gamma \omega = \sum_1 1_{T^\circ_n O_i}(g^{(n)} \omega) \circ T_i^{-n}$, we get by Lemma 4.5 that for each $\zeta \in Z(R)$

$$\| (\rho_\zeta \cdot 1_{O_i} L^p_\gamma \omega) \circ \Phi_\zeta \|_{H^s_p} \leq c C_\# (D^e_n)^{p-1} \sum_{i \in I^n} \| (\rho_\zeta 1_{O_i} 1_{T^\circ_n O_i}(g^{(n)} \omega) \circ T_i^{-n}) \circ \Phi_\zeta \|_{H^s_p}.$$  

Summing over $\zeta \in Z(R)$, we obtain

$$\| L^p_\gamma \omega \|_{\Phi,R} \leq c C_\# (D^e_n)^{p-1} \sum_{\zeta \in Z(R), i \in I^n} \| (\rho_\zeta 1_{O_i} 1_{T^\circ_n O_i}(g^{(n)} \omega) \circ T_i^{-n}) \circ \Phi_\zeta \|_{H^s_p}.$$  

For $i \in I$, let $U_{i,j,2}$, $1 \leq j \leq N_i$, be arbitrary open sets covering a fixed neighborhood $\tilde{O}_i$ of $\overline{O}_i$, such that $\overline{U_{i,j,2}} \subset U_{i,j,1}$ (they do not depend on $n$, $R$, or any other choices). For each $\zeta \in Z(R)$, and $i = (i_0, \ldots, i_{n-1}) \in I^n$ such that $T_i^n \tilde{O}_i$ intersects $A(\zeta)$, the point $T_i^{-n}(q_\zeta)$ belongs to $\tilde{O}_i$, if $R$ is large enough, we can therefore consider $k$ such that it belongs to $U_{i_k,k,2}$. Then $\sum_{i \in I^n} \rho_{i_k,k,\ell}$ is equal to 1 on a neighborhood of fixed size of $T_i^{-n}(q_\zeta)$, so that $\sum_{i \in I^n} \rho_{i_k,k,\ell} \circ T_i^{-n}$ is equal to 1 on $A(\zeta)$ if $R$ is large enough (depending on $n$ but not on $\Phi$ or $\zeta$). Since the intersection multiplicity of the supports of the $\rho_{i_k,k,\ell} \circ T_i^{-n}$ is uniformly bounded, Lemma 4.5 gives, if $R \geq R(n)$ (chosen uniformly in $\Phi$, $\zeta$, $k$, $i$),

$$\| (\rho_\zeta 1_{O_i} 1_{T^\circ_n O_i}(g^{(n)} \omega) \circ T_i^{-n}) \circ \Phi_\zeta \|_{H^s_p} \leq c R \sum_{i \in Z(R)} \| (\rho_\zeta 1_{O_i} 1_{T^\circ_n O_i}(\rho_{i_k,k,\ell} \cdot g^{(n)} \omega) \circ T_i^{-n}) \circ \Phi_\zeta \|_{H^s_p}.$$  

\(^10\)Elements of $L^\infty$ are defined almost everywhere, and the transfer operator is defined initially on $L^\infty$, so the fact that $\bigcup_i O_i = X_0$ only modulo a zero Lebesgue measure set is irrelevant.
Taking $R$ large enough and summing over $\zeta \in \mathcal{Z}(R)$, $i \in I^n$ and $k \in \{1, \ldots, N_{i_0}\}$ such that $T_{i_0}^{-n}(q_\zeta) \in U_{i_0, k, 2}$, we get (writing $\zeta' = (i_0, k, \ell) \in \mathcal{Z}(R)$)

\[
(5.2) \left\| L_\phi \omega \right\|_{\Phi, R}^p \leq c C_\# (D^p_\omega)^{p-1} \sum_{\zeta, i, \zeta'} \left\| (\rho_{\zeta} 1_{O_\zeta} 1_{T_{i_0}^n} (\rho_{\zeta'} \cdot g^{(n)} \omega) \circ T_{i_0}^{-n}) \circ \Phi_{\zeta} \right\|_{H^{p,s}}^p,
\]

where the sum is restricted to those $(\zeta, i, \zeta')$ such that the support of $\rho_{\zeta'}$ is included in $O_i$, the support of $\rho_{\zeta}$ is included in $T_i O_i$, and $O_{\zeta'} = O_i$ (this restriction will be implicit in the rest of the proof).

**Second step: Getting rid of the characteristic function.** We claim that, if $R$ is large enough, then for any $\zeta, i, \zeta'$ as in the right-hand-side of (5.2)

\[
(5.3) \left\| (\rho_{\zeta} 1_{O_\zeta} 1_{T_{i_0}^n} (\rho_{\zeta'} \cdot g^{(n)} \omega) \circ T_{i_0}^{-n}) \circ \Phi_{\zeta} \right\|_{H^{p,s}}^p \leq C_\# n^p \left\| (\rho_{\zeta} (1_{O_{\zeta'}} \rho_{\zeta'} \cdot g^{(n)} \omega) \circ T_{i_0}^{-n}) \circ \Phi_{\zeta} \right\|_{H^{p,s}}^p.
\]

Note that $1_{T_{i_0}^n} = 1_{T_{i_0}^n} (1_{O_\zeta} \circ T_{i_0}^{-n})$. Hence, to prove this inequality, it is sufficient to show that the multiplications by $1_{O_\zeta} \circ \Phi_{\zeta}$ and by $1_{T_{i_0}^n} \circ \Phi_{\zeta}$ act boundedly on $H^{p,s}_v$, with norms bounded respectively by $C_\#$ and $C_\# n$. We shall show the latter, the former is similar. We wish to exploit our transversality assumption to apply Lemma 4.2. Write $\zeta = (i, j, m)$. Since the support of $\rho_{\zeta} \circ (\kappa_R^{-1}) = \rho_m$ is contained in the ball $B(m, d)$, it is even sufficient to prove the bounded multiplier property for distributions supported in $\phi_{\zeta}^{-1} B(m, d)$. In $B(m, d)$, the set $\kappa_R^R(T_{i_0}^n) O_i$ is the intersection of the sets $\kappa_R^R(T_{i_0}^{n-k}) O_i)$. The boundary of this set is locally a finite union of smooth hypersurfaces, namely the images of the hypersurfaces forming the boundary of $O_i$ (their number is therefore bounded by a constant $L$). All those hypersurfaces are transverse to the stable cone $C_{i,j}^t$. If $R$ is large enough (depending on $T$ and $n$ but not on $m$ or $\Phi$), all those boundaries are almost hyperplanes in $B(m, d)$. In particular, a smooth curve $\Gamma$ whose tangent vector is always contained in the stable cone $C_{i,j}^t \cup (a$ sufficiently small enlargement $C_{i,j}^t(\epsilon_\#)$ of this cone) will intersect each of those hypersurfaces in at most one point. Therefore, if $R$ is large enough, $\Gamma$ will intersect $\kappa_R^R(T_{i_0}^{n-k}) O_i) = 1_{O_{i_0}}$ along at most $L$ intervals.

Consider a basis $(e_1, \ldots, e_d)$ of $\mathbb{R}^d$ such that $e_{d+1}, \ldots, e_d$ form a basis of $\{0\} \times \mathbb{R}^d$, and $e_1, \ldots, e_{d+1}$ are very close to $\{0\} \times \mathbb{R}^d$. Then the image under $\phi_{\zeta}$ of any line directed by one of the vectors $e_1, \ldots, e_d$ is a curve $\Gamma$ whose tangent vector is everywhere contained in $C_{i,j}^t(\epsilon_\#)$. Therefore, if $R$ is large enough, the set $\phi_{\zeta}^{-1} \kappa_R^R(T_{i_0}^{n-k}) O_i) \cap \Gamma$ intersects lines directed by one of those vectors along at most $L$ connected components. The intersection of those sets is $\phi_{\zeta}^{-1} \kappa_R^R(T_i O_i)$. Therefore, Lemma 4.2 (together with our assumption that $1/p - 1 < s < 0 < t < 1/p$) implies that the multiplication by the characteristic function of this set acts boundedly on $H^{p,s}_v$, with a norm bounded by $nL$, proving (5.3).

Combining (5.3) with (5.2), we get

\[
(5.4) \left\| L_\phi \omega \right\|_{\Phi, R}^p \leq c C_\# n^p (D^p_\omega)^{p-1} \sum_{\zeta, i, \zeta'} \left\| (\rho_{\zeta} (1_{O_{\zeta'}} \rho_{\zeta'} \cdot g^{(n)} \omega) \circ T_{i_0}^{-n}) \circ \Phi_{\zeta} \right\|_{H^{p,s}}^p.
\]

**Third step: Using the composition lemma.** The right hand side of (5.4) involves a sum over $\zeta'$ and $\zeta$, and has therefore too many terms. In this step, we shall use Lemma 3.3, to pull the charts $\Phi_{\zeta}$ back at time $-n$, and glue some of the pulled-back charts together to get rid of the summation over $\zeta$. 

Let us partition \( Z(R) \) into finitely many subsets \( Z^1, \ldots, Z^E \) such that \( Z^e \) is included in one of the sets \( Z_{i,j}(R) \), and \(|m-m'| \geq C \) whenever \((i,j, m) \neq (i,j, m') \in \mathcal{Z}^e \). The number \( E \) may be chosen independently of \( n \).

We shall prove the following: For any \( \zeta' \in Z(R) \), any \( i \in I^n \) (such that the support of \( \rho_{\zeta'} \) is included in \( O_i \) and \( O_{\zeta'} = O_{u} \)) and any \( 1 \leq e \leq E \), there exists an admissible chart \( \Phi' = \Phi'_{\zeta',1,e} \in \mathcal{F}(\zeta') \) such that

\[
\sum_{\zeta \in \mathcal{Z}^e} \| \rho_\zeta (1_{O_{\zeta'} \cap O_{\zeta}} \cdot g(n)) \circ T_1^{-n} \|_{H_t,s}^p \leq \chi_n \| (1_{O_{\zeta'} \cap O_{\zeta}} \cdot \omega) \circ \Phi'_{\zeta',1,e} \|_{H_t,s}^p ,
\]

where

\[
\chi_n = \| \det DT^n | \max(\lambda_{\omega,n}, \lambda^{-e}_{\omega,n}(s+\ell)\rho) \|_{L_\infty}.
\]

As always, the sum on the left hand side of (5.5) is restricted to those values of \( \zeta \) such that the support of \( \rho_{\zeta} \) is included in \( T_1 \).

Let us fix \( \zeta', i \) and \( e \) as above, until the end of the proof of (5.5). All the objects we shall now introduce shall depend on these choices, although we shall not make this dependence explicit to simplify the notations. Let \( i, j \) be such that \( \mathcal{Z}^e \subset Z_{i,j}(R) \), and let \( \mathcal{M} = \{ m \mid (i,j, m) \in \mathcal{Z}^e \} \). Since the points in \( \mathcal{M} \) are distant of at least \( C_1 \), Lemma 3.3 will apply.

Increasing \( R \), we can ensure that the map

\[
T := \kappa_{i,j}^R \circ T_i^n \circ (\kappa_i^R)^{-1}
\]

is arbitrarily close to its differential \( M = DT(\ell) \) at \( \ell := \kappa_{\zeta'}(q_{\zeta'}) \), i.e., the map \( (T^{-1}[+ T(\ell)] - \ell) \circ M \) is close to the identity in \( C^{1+\alpha} \), say on the ball \( B(0,2d) \). Moreover, recalling the notation from the beginning of Section 3, the matrix \( M \) sends \( C_{\zeta'} \) to \( C_{i,j} \), compactly, and

\[
C_\# \geq \lambda_u(M, C_{\zeta'}, C_{i,j})/\lambda_u(n)(q_{\zeta'}) \geq C_\#^{-1},
\]

with similar inequalities for \( \lambda_\zeta \) and \( \lambda_u \). Since \( T \) is uniformly hyperbolic and satisfies the bunching conditions (2.3) and (2.4), we can ensure by taking \( n \) large enough that \( M \) satisfies (3.1) for the constants \( \epsilon_1 \) and \( C_1 \). By Lemma A.3, since the map \( (T^{-1}[+ T(\ell)] - \ell) \circ M \) is close to the identity on \( B(0,2d) \), there exists a diffeomorphism of \( \mathbb{R}^d \), close to the identity and coinciding with this map on \( B(0, d) \). Composing with \( M^{-1} \) and translating, we obtain an extension of \( T^{-1} \), coinciding with \( T^{-1} \) on \( B(T(\ell), d) \), and still denoted by \( T^{-1} \). Taking \( R \) large enough, we can ensure that \( \| (T^{-1}[+ T(\ell)] - \ell) \circ M - id \|_{C^{1+\alpha}} \leq \epsilon_1 \).

We may therefore apply Lemma 3.3 (see also Remark 3.4), and we obtain a block diagonal matrix \( D \), a chart \( \phi' \) around \( \ell \), and diffeomorphisms \( \Psi_m, \Psi \) such that, for any \( m \in \mathcal{M} \) of those elements in \( \mathcal{M} \) for which \( \rho_{\zeta} \cdot \rho_{\zeta'} \circ T_i^n \) is nonzero,

\[
\sum_{\zeta \in \mathcal{Z}^e} \| (\rho_{\zeta'} (1_{O_{\zeta'} \cap O_{\zeta}} \cdot g(n)) \circ T_1^{-n}) \circ \Phi'_{\zeta'} \|_{H_t,s}^p
\]

on the set where \( (\rho_{\zeta} \cdot \rho_{\zeta'} \circ T_i^n) \circ \phi_{\zeta} \) is nonzero.

Writing \( \omega'(1_{O_{\zeta'} \cap O_{\zeta}} \cdot g(n)) \circ (\kappa_i^R)^{-1} \), we have (recall that \( (i,j) \) is fixed so that \( \mathcal{Z}^e \subset Z_{i,j}(R) \))

\[
\sum_{\zeta \in \mathcal{Z}^e} \| (\rho_{\zeta'} (1_{O_{\zeta'} \cap O_{\zeta}} \cdot g(n)) \circ T_1^{-n}) \circ \Phi'_{\zeta'} \|_{H_t,s}^p
\]

\[
= \sum_{m \in \mathcal{M}} \| (\rho_m \circ \phi_{i,j,m} \cdot \omega' \circ T^{-1} \circ \phi_{i,j,m} ) \|_{H_t,s}^p
\]

\[
= \sum_{m \in \mathcal{M}} \| (\rho_m \circ \phi_{i,j,m} \circ \Psi_m^{-1} \cdot \omega' \circ \phi_{\zeta'} \circ D^{-1} \circ \Psi_m ) \|_{H_t,s}^p.
\]
Using the notations and results of Lemma 3.3, the terms in this last equation are of the form $v \circ \Psi_m$, where $v$ is a distribution supported in $\Psi_m(\phi_{i,j,m}^{-1}(B(m,d))) \subset B(\Pi m, C_0^{1/2}/2)$. Since the range of $\Psi_m$ contains $B(\Pi m, C_0^{1/2})$, and since $at + |s_0| < \alpha$, Lemma 4.7 gives $\|v \circ \Psi_m\|_{H^s_{r,s}} \leq C_{#} \|v\|_{H^s_{r,s}}$, yielding a bound

$$C_{#} \sum_{m \in M'} \left\| \rho_m \circ \phi_{i,j,m} \circ \Psi_m^{-1} \cdot \omega' \circ \phi' \circ \Psi \circ D^{-1} \right\|_{H^s_{r,s}}^p.$$ 

The functions $\rho_m \circ \phi_{i,j,m} \circ \Psi_m^{-1}$ have a bounded $C^1$ norm, and are supported in the balls $B(\Pi m, C_0^{1/2}/2)$, whose centers are distant by at least $C_0$, by Lemma 3.3 (a). Therefore, by Lemma 4.3, the last expression is bounded by

$$C_{#} \left\| \omega' \circ \phi' \circ \Psi \circ D^{-1} \right\|_{H^s_{r,s}}^p.$$ 

We may apply Lemma 4.6 to the composition with $D^{-1}$ (to obtain an improvement in the $H^s_{r,s}$ norm, up to compact terms). Since $\omega'$ is supported in $B(t, C_0^{1/2}/2)$ while the range of $\Psi$ contains $B(t, C_0^{1/2})$ (by Lemma 3.3), Lemma 4.7 implies that the composition with $\Psi$ is bounded. Summing up, we obtain

$$(5.9) \sum_{\zeta \in Z} \left\| (\rho_\zeta(1_{O_\zeta} \cdot \gamma^{(n)}) \circ T_{i}^{-n}) \circ \Phi_\zeta \right\|^p_{H^s_{r,s}} \leq \epsilon \chi_n(\omega) \left\| (1_{O_\zeta} \cdot \gamma^{(n)}) \circ (\eta^R)^{-1} \circ \phi' \right\|^p_{H^s_{r,s}},$$

where

$$\chi_n(\omega) = \left( \det DT^{n} \right) \max(\lambda_{t,n}, \lambda_{t,n}^{-1})^p \left( \omega \right).$$

Since $(\eta^R)^{-1}$ contracts by a factor $1/R$, we can ensure by increasing $R$ that the $C^\gamma$ norm of $\gamma^{(n)} \circ (\eta^R)^{-1}$ on $B(t, d)$ is bounded by $C_{#} \|\gamma^{(n)}(\omega)\|$ (recall that, by assumption, $\omega$ belongs to $C^\gamma$ for some $\gamma > t + |s_0|$). Hence, (5.9) and Lemma 4.1 yield

$$\sum_{\zeta \in Z} \left\| (\rho_\zeta(1_{O_\zeta} \cdot \gamma^{(n)}) \circ T_{i}^{-n}) \circ \Phi_\zeta \right\|^p_{H^s_{r,s}} \leq \epsilon \chi_n \left\| (1_{O_\zeta} \cdot \gamma^{(n)}) \circ (\eta^R)^{-1} \circ \phi' \right\|^p_{H^s_{r,s}}.$$ 

This concludes the proof of (5.5). Summing over all possible values of $\zeta_1, \zeta_2$ and, $\epsilon$, we obtain

$$(5.10) \left\| L_n^p \omega \right\|_{\Phi, R} \leq C \epsilon \chi_n^{n^p}(D_n^p)^{-1} \chi_n \sum_{\zeta_1} \sum_{\zeta_2} \sum_{\epsilon} \left\| (1_{O_\zeta} \cdot \gamma^{(n)}) \circ \Phi_{\zeta_1, \zeta_2, \epsilon} \right\|^p_{H^s_{r,s}}.$$ 

Fourth step: Conclusion. The right hand side of (5.10) is essentially of the form $\|\omega\|_{\Phi, R}$ for some family of admissible charts $\Phi'$, with the difference that to a point $q_{\zeta_1}$ for $\zeta_1 \in \mathcal{Z}(R)$ correspond several admissible charts around it. Since $E$ is independent of $n$, the number of those charts around $q_{\zeta_1}$ is at most $C_{#} \cdot \text{Card}\{\zeta_1 \mid \mathcal{O}_{\zeta_1} \cap A(\zeta_1) \neq \emptyset\}$. If $R$ is large enough, we can ensure that this quantity is bounded by the intersection multiplicity of the sets $\mathcal{O}_{\zeta_1}$, which is at most $D_n^b$ by construction. Therefore, we obtain

$$\left\| L_n^p \omega \right\|_{\Phi, R} \leq C \epsilon \chi_n^{n^p}(D_n^p)^{-1} D_n^b \chi_n \left\| \omega \right\|_{H^s_{r,s}(R)}.$$ 

Proof of Proposition 2.15. Remark 3.6 shows that the charts $\phi'$ we constructed in the third step of the proof of Lemma 5.1 can be defined on larger balls, and with better bounds. In particular, these new charts will be admissible when looked at a scale $R'$, for any $R'/2 \leq R' \leq 2R$. The proof of Lemma 5.1 therefore gives the following statement:
For large enough \( n \), say \( n \geq n_1 \), there exists \( R_1(n) > 0 \) such that, whenever \( R \geq R_1(n) \) and \( R' \in [R/2, 2R] \), the operator \( L_g^n \) maps continuously \( H^{1,\alpha}_p(R) \) to \( H^{1,\alpha}_p(R') \).

In particular, for any \( R, R' \geq R_1(n_1) \), there exists an integer \( K = K(R, R') \) such that, whenever \( k \geq K \), \( L_g^{kn} \) maps \( H^{1,\alpha}_p(R) \) to \( H^{1,\alpha}_p(R') \). If \( R \) is larger than \( \max_{n_1 \leq n \leq 2n_1} R(n) \), the operator \( L_g^n \) maps \( H^{1,\alpha}_p(R) \) to itself for any \( n_1 \leq n \leq 2n_1 \). Therefore, \( L_g^N \) maps \( H^{1,\alpha}_p(R) \) to \( H^{1,\alpha}_p(R') \) when \( N \geq (K + 1)n_1 \), since \( N \) can then be written as \( kn_1 + n \) with \( k \geq K \) and \( n_1 \leq n \leq 2n_1 \). \( \square \)

**Appendix A. Calculus for some classes of maps**

This appendix groups some straightforward results about classes of maps \( \mathcal{D} \) and \( \mathcal{K} \) which appear in the proofs of Lemma 2.8 and Lemmas 3.3–3.5 (together with an easy result, which is useful for the proof of Lemma 5.1).

**A.1. The class \( \mathcal{D} \).** For \( C_\# > 0 \), let us denote by \( \mathcal{D}(C_\#) \) the class of \( C^1 \) maps \( f \) defined on an open subset of \( \mathbb{R}^d \), satisfying

\[
C_\#^{-1} \left| z - z' \right| \leq \left| f(z) - f(z') \right| \leq C_\# \left| z - z' \right|,
\]

for any \( z, z' \) in the domain of definition of \( f \). It follows that \( f \) is a local diffeomorphism, and that \( \|Df\| \leq C_\# \), \( \| (Df)^{-1} \| \leq C_\# \).

**Lemma A.1.** Assume that \( f(x, y) = (g(x, y), y) \) is defined on a set \( A_1 \times A_2 \) where \( A_1 \) and \( A_2 \) are convex, that \( |Dg| \leq C \), and that \( |g(x, y) - g(x', y)| \geq C^{-1} |x - x'| \) for some \( C > 0 \). Then \( f \in \mathcal{D}(C_\#) \), for some constant \( C_\# \) depending only on \( C \).

**Proof.** Since the second coordinate of \( f(x, y) \) is equal to \( y \), while the derivative of \( f \) is bounded by \( C \), we have

\[
\left| y - y' \right| \leq \left| f(x, y) - f(x', y') \right| \leq C_\# \left( |x - x'| + \left| y - y' \right| \right),
\]

for some constant \( C_\# \) depending only on \( C \). This proves the (trivial) upper bound in \((A.1)\).

Consider now two points \( z = (x, y), z' = (x', y') \in A_1 \times A_2 \). If \( |y - y'| \geq C^{-1} |x - x'| / (2C_\#) \), we have in particular \( |y - y'| \geq C_\# |z - z'| \) for some \( C_\# \), and we get from \((A.2)\) that \( |f(z) - f(z')| \geq C_\# |z - z'| \). Otherwise,

\[
|f(x, y) - f(x', y')| \geq |f(x, y) - f(x', y)| - |f(x', y) - f(x', y')| \geq C^{-1} |x - x'| - C_\# |y - y'| \geq C^{-1} |x - x'| / 2.
\]

This proves the lower bound in \((A.1)\) in all cases. \( \square \)

**Lemma A.2.** Let \( f \in \mathcal{D}(C_\#) \), and assume that the domain of definition of \( f \) contains a ball \( B(z, r) \). Then the range of \( f \) contains \( B(f(z), r'/C_\#) \).

**Proof.** Let \( r' < r \), and consider \( A = f(B(z, r')) \cap B(f(z), r'/C_\#) \). Since \( f \) is a local diffeomorphism, this is an open subset of \( B(f(z), r'/C_\#) \). Moreover, if \( |z' - z| = r' \), then \( f(z') \) does not belong to \( B(f(z), r'/C_\#) \), since \( |f(z') - f(z)| \geq |z' - z| / C_\# = r'/C_\#. \) Therefore, \( A \) is also equal to \( f(B(z', r)) \cap B(f(z), r'/C_\#) \). This is a closed subset of \( B(f(z), r'/C_\#) \), since \( f(B(z', r)) \) is compact.

Finally, \( A \) is open and closed in \( B(f(z), r'/C_\#) \). By connectedness, it coincides with this whole ball. In particular, the range of \( f \) contains \( B(f(z), r'/C_\#) \). Letting \( r' \) tend to \( r \), we conclude the proof. \( \square \)

Let us also mention the following easy result, which is useful for the proof of Lemma 5.1.
Lemma A.3. Let $\alpha \in (0,1]$ and let $f : B(0,1) \to \mathbb{R}^d$ be a diffeomorphism such that $\|f - \text{id}\|_{C^{1+\alpha}}$ is small enough. Then there exists a diffeomorphism $\tilde{f}$ of $\mathbb{R}^d$, coinciding with $f$ on $B(0,1/2)$, and such that $\|\tilde{f} - f\|_{C^{1+\alpha}} \leq C_\alpha \|f - \text{id}\|_{C^{1+\alpha}}$, for some universal constant $C_\alpha$ depending only on the dimension $d$.

Proof. Let us write, for $z \in B(0,1)$, $f(z) = z + \psi(z)$ with $\|\psi\|_{C^{1+\alpha}}$ small. We may define the required extension $f$ of $f$ by $\tilde{f}(z) = z + \gamma(z)\psi(z)$ where $\gamma$ is $C^\infty$ equal to $1$ on $B(0,1/2)$ and supported in $B(0,1)$. If $\|\psi\|_{C^{1+\alpha}}$ is small enough, then $\langle D\tilde{f}v,v\rangle \geq |v|^2/2$, from which it follows that $|\tilde{f}(z) - \tilde{f}(z')| \geq |z - z'|/2$. Therefore, $\tilde{f}$ belongs to the class $\mathcal{D}(2)$. By Lemma A.2, it is surjective, hence it is a diffeomorphism of $\mathbb{R}^d$.

A.2. The class $\mathcal{K}$. Let us fix $\alpha \in (0,1]$ and $\beta \in (0,\alpha)$. We denote by $\mathcal{K} = \mathcal{K}^{\alpha,\beta}$ the class of matrix-valued functions $K$ on $\mathbb{R}^d$ such that, for some constant $C$ and for all $x,x' \in \mathbb{R}^{d_2}$ and all $y,y' \in \mathbb{R}^{d_1}$,

(A.3) $|K(x,y)| \leq C$,
(A.4) $|K(x,y) - K(x',y)| \leq C|x-x'|^{\beta}$,
(A.5) $|K(x,y) - K(x,y')| \leq C|y-y'|^\alpha$,
(A.6) $|K(x,y) - K(x',y) - K(x,y') + K(x',y')| \leq C|x-x'||y-y'|^{\alpha - \beta}$.

If $K \in \mathcal{K}$, we write $\|\mathcal{K}\|$ for the the smallest $C$ satisfying the inequalities above. We write $\mathcal{K}(C)$ for the functions in $\mathcal{K}$ with $\|\mathcal{K}\| \leq C$.

For instance, any bounded $\alpha$-Hölder continuous function $K$ belongs to $\mathcal{K}$ to obtain (A.6), treat separately the cases $|x-x'| \leq |y-y'|$ and $|x-x'| > |y-y'|$. Note also that if $K$ is $C^1$ then the left-hand-side of (A.6) can be rewritten as $\int_0^{y'} \partial_{y'} K(x,t) - \partial_{y'-y'} K(x',t) dt$, i.e., it is a finite-difference-type expression for $\partial_x \partial_{y'} K$.

Proposition A.4. A function in $\mathcal{K}$ satisfies

(A.7) $|K(x,y) - K(x',y')| \leq 3 \|\mathcal{K}\| (|x-x'| + |y-y'|)^\beta$.

If $K,K' \in \mathcal{K}$, then $K+K' \in \mathcal{K}$, with $\|K+K'\| \leq \|K\| + \|K'\|$. Moreover, $KK' \in \mathcal{K}$, with $\|KK'\| \leq 6 \|K\| \|K'\|$. Finally, if $K$ is everywhere invertible and $|K|^{-1} \leq h$ for some finite number $h$, then $K^{-1} \in \mathcal{K}$ and $\|K^{-1}\| \leq 5 \max(1,h^3) \max(1,\|K\|)^3$.

Proof. Notice first that we have

(A.8) $|K(x,y) - K(x,y')| \leq 2 \|\mathcal{K}\| |y-y'|^{\alpha - \beta}$.

Indeed, this follows from (A.5) if $|y-y'| \leq 1$, and from (A.3) if $|y-y'| > 1$. This inequality also holds if $|y-y'|^{\alpha - \beta}$ is replaced with $|y-y'|^\beta$ (with the same proof). Therefore, by (A.4),

\[
|K(x,y) - K(x',y')| \leq |K(x,y) - K(x',y)| + |K(x',y) - K(x',y')| \\
\leq \|\mathcal{K}\| |x-x'|^{\beta} + 2 \|\mathcal{K}\| |y-y'|^{\beta} \leq 3 \|\mathcal{K}\| \max(|x-x'|,|y-y'|)^\beta.
\]

(A.7) follows.

Consider now $K,K' \in \mathcal{K}$. It is trivial that $\|K+K'\| \leq \|K\| + \|K'\|$. We turn to $KK'$. Let us write $a,b,c,d$ for $K(x,y), K(x',y), K(x',y'), K(x,y')$. Similarly, we use $a',b',c',d'$ for $K'$. The inequality (A.3) for $KK'$ is trivial, (A.4) follows from the equality $aa'-bb'=a(a'-b')+(a-b)b'$, and (A.5) is similar. For (A.6), we use the identity

\[
aa' - bb' - cc' + dd' = c(a'b'-c'd') + (a+b-c+d)d' + (a-c)(a'-b') + (a-b)(b'-d'),
\]
and the bounds for \( a - c, a' - b', a - b \) and \( b' - d' \) given by (A.4) and (A.8). This concludes the proof for \( K'K' \).

Finally, assume \(|K^{-1}1| \leq h\). Then (A.3) holds for \( K^{-1}1 \). Moreover, (A.4) follows from the equality \(|a^{-1} - b^{-1}| = |a^{-1}(b - a)b^{-1}| \leq h^2|a - b|\). (A.5) is similar. For (A.6), we use the identity

\[
\begin{align*}
a^{-1} - b^{-1} - c^{-1} + d^{-1} &= a^{-1}(b + c - a - d)b^{-1} \\
&\quad + a^{-1}(c - a)c^{-1}(d - c)b^{-1} + c^{-1}(d - c)b^{-1}(d - b)d^{-1},
\end{align*}
\]

and the bounds (A.4) and (A.8).

We recall that the subsets \( \{x\} \times \mathbb{R}^d \) of \( \mathbb{R}^d \) are called “stable leaves” of \( \mathbb{R}^d \) in this article.

**Proposition A.5.** Let \( \Psi : \mathbb{R}^d \to \mathbb{R}^d \) send stable leaves to stable leaves, and assume that its best Lipschitz constant \( L \) is finite. Then, for \( K \in K \), the function \( K \circ \Psi \) also belongs to \( K \), and \(|K \circ \Psi| \leq 3 \max(1, L)|K|\).

**Proof.** The inequality (A.3) is trivial for \( K \circ \Psi \). For (A.4), we write using (A.7)

\[
|K \circ \Psi(x, y) - K \circ \Psi(x', y)| \leq 3 \|K\| \|d\Psi(x, y), \Psi(x', y)\|^\beta
\]

\[
\leq 3 \|K\| L^\beta \|d(x, y), (x', y)\|^\beta \leq 3 \|K\| \max(1, L)|x - x'|^\beta.
\]

(A.5) for \( K \circ \Psi \) follows from (A.5) for \( K \) and from the fact that \( \Psi \) sends stable leaves to stable leaves and is Lipschitz continuous.

We turn to (A.6). We write \( \Psi(x, y) = (x_1, y_1), \Psi(x, y') = (x_2, y_2) \) and \( \Psi(x', y') = (x_2', y_2') \).

Assume first \(|y - y'| \leq |x - x'|\). Then

\[
|K(x_1, y_1) - K(x_1, y'_1) - K(x_2, y_2) + K(x_2, y'_2)|
\]

\[
\leq |K(x_1, y_1) - K(x_1, y'_1)| + |K(x_2, y_2) - K(x_2, y'_2)|
\]

\[
\leq \|K\| |y_1 - y'_1| + \|K\| |y_2 - y'_2| < \|K\| L^\alpha |y - y'|^\alpha.
\]

Since \( L^\alpha \leq \max(1, L) \) and \(|y - y'|^\alpha \leq |x - x'|^\beta |y - y'|^\alpha - \beta \), this is the desired conclusion. Assume now \(|x - x'| \leq |y - y'|\). Then

\[
|K(x_1, y_1) - K(x_1, y'_1) - K(x_2, y_2) + K(x_2, y'_2)|
\]

\[
\leq |K(x_1, y_1) - K(x_1, y'_1) - K(x_2, y_2) + K(x_2, y'_2)|
\]

\[
+ |K(x_2, y_2) - K(x_2, y'_2)| + |K(x_2, y'_2) - K(x_2, y'_2)|.
\]

\[
\leq \|K\| |x_1 - x'|^\beta |y_1 - y'_1| + \|K\| |y_2 - y'_2| + \|K\| |y_2 - y'|^\alpha.
\]

Since \( \Psi \) is Lipschitz continuous, we have \(|x_1 - x| \leq L|x - x'|\) and \(|y_1 - y'_1| \leq L|y - y'|\). Moreover,

\[
|y_2 - y'_1| \leq d((x_1, y_1), (x_2, y_2)) = d(\Psi(x, y), \Psi(x', y)) \leq Ld((x, y), (x', y)) = L|x - x'|.
\]

Since \(|x - x'| \leq |y - y'|\), we obtain \(|y_2 - y'_1|^\alpha \leq L^\alpha |x - x'|^\alpha \leq \max(1, L)|x - x'|^\beta |y - y'|^\alpha - \beta \). Moreover, \(|y'_2 - y'_1| \) satisfies a similar inequality. Finally, (A.9) is bounded by \(3 \|K\| \max(1, L)|x - x'|^\beta |y - y'|^\alpha - \beta \). This concludes the proof.

**Remark A.6.** If \( A_1 \) and \( A_2 \) are convex subsets of, respectively, \( \mathbb{R}^{d_1} \) and \( \mathbb{R}^{d_2} \), we can define analogously a space \( K(C, A_1 \times A_2) \) of matrix-valued functions defined on \( A_1 \times A_2 \) and satisfying (A.3)–(A.6). The previous results also hold for this space, with the same proofs, up to the following small modification: In Proposition A.5, if \( K \) is defined on \( A_1 \times A_2 \), we need to require that \( \Psi \) be defined on \( A_1' \times A_2' \) with \( \Psi(A_1' \times A_2') \subset A_1 \times A_2 \). Successive applications of the proposition in the proof of Lemma 3.5 will require stronger conditions. The careful reader is invited to check that this does not cause any problems in the proof of Lemma 3.5.
Appendix B. Convex transversality

We prove the claims made after Definition 2.1. Any cone $\{x \leq |Ay|\}$ defined via an injective linear map $A$ can be reduced to the standard cone $C = \{(x, y) \in \mathbb{R}^d \mid |x| \leq |y|\}$ by a change of coordinates. Therefore, it suffices to prove that for any vector space $E$ so that $C \cap E = \{0\}$, then $C \cap (E + w)$ is convex for all $w \in \mathbb{R}^d$.

Proof. Pick $z_1, z_2$ in $C \cap (E + w)$, we want to show that the segment $[z_1, z_2]$ is included in $C \cap (E + w)$. The line directed by $z_0 := z_2 - z_1$ is contained in $E$, so $z_0 = (x_0, y_0) \notin C$, i.e., $|y_0|^2 > |x_0|^2$.

Let $D = \{(x_1 + tx_0, y_1 + ty_0) \mid t \in [0, 1]\}$ be the segment between $z_1 = (x_1, y_1)$ and $z_2$. The leading coefficient of the polynomial $\Phi(t) := |y(t)|^2 - |x(t)|^2 = |y_1 + ty_0|^2 - |x_1 + tx_0|^2$ is $|y_0|^2 - |x_0|^2 > 0$. Therefore, the set $\{t \mid \Phi(t) \leq 0\}$ is convex, i.e., $C \cap D$ is convex. Since $z_1$ and $z_2$ belong to $C \cap D$, we find $D \subset C \cap D$, as desired. □
